# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1565

JULY 6, 1918.

VOL. XXXI.

## DIFFERENTIAL DIAGNOSIS.

Differential diagnosis is always an important subject in practice, and is never more so than when a scheduled disease is one of the possibilities. Perhaps there are many clinicians who have yet neither fully informed themselves regarding the many comparatively unimportant animal affections which may be confounded with scheduled diseases, nor become sufficiently acquainted with the frequency and nature of atypical cases of the latter. The subject is one which deserves close study; but the study is far from easy.

Its intricacy is well illustrated by the long and comprehensive paper upon foot-and-mouth disease recently read by Mr. A. H. Berry, at a meeting of the Midland Counties V.M.A. Many readers will be surprised at the number and variety of unscheduled affections, some of them little noticed in our literature, which Mr. Berry describes as liable to be confused with foot-and-mouth disease. Even experienced country practitioners may learn something from his description, while it will be a revelation to some younger ones. The paper well shows the difficulties which not uncommonly attend veterinary preventive work in the field; although it concerns a disease which, in its typical form, is usually easily diagnosed.

Swine fever is another example. All practitioners know the frequent difficulty or impossibility of deciding upon its existence during life in isolated cases, though not all are sufficiently familiar with some of the affections which may be confused with it. Rinderpest, which may very possibly at least threaten to visit us from Europe in the next few years, is another disease which may present equal difficulties in the differential diagnosis of isolated cases. Broadly speaking, scheduled diseases in their most typical forms are easily recognised by the skilled veterinarian; but they may also appear in forms which are difficult to diagnose, and many other conditions may simulate the "sufficiently to mislead the inexperienced.

The Board of Agriculture whole-time veterinary officers are specially trained to cope with these difficulties. The general practitioner has no such advantage, but may well give himself some special training in addition to his college one. Two things are necessary for the working clinician to attain his maximum fitness to deal with scheduled disease. Firstly, the study of scheduled diseases themselves as far as possible, whether or not he has frequent opportunities of observing them. Much information can be gained regarding both their typical and atypical forms from the literature; and text-book study alone might prevent serious mistakes in some cases.

Secondly, to lose no opportunity of increasing his familiarity with the many diseases, less fully described in the literature but more or less commonly met with in practice, which may be confused with scheduled ones. Opportunities for this latter study in practice are more frequent than they used to be; for probably veterinary surgeons have never been so often consulted regarding the minor ailments of stock as at present.

The country practitioner's experience of the diseases of cattle, sheep, and pigs is now more extensive and varied than in the old days. This, properly used, is capable of indirectly greatly increasing his capacity to deal with cases which suggest scheduled disease.

## A NOTE ON THE ACTION OF MORPHIA ON A DOG.

By HENRY TAYLOR, F.R.C.V.S., Haywards Heath.

A small pug recently had a tumour on the tarsus of the left hind leg and it became necessary to remove it. The animal was normally rather nervous, so morphia seemed the ideal drug to use as an anæsthetic. Half a grain was accordingly injected subcutaneously, but instead of the usual effect, the dog became very excited, the expression of the face reminded one of a frightened wild animal, and she walked up and down behind the bars of the kennel exactly like a caged beast. There was no sickness nor passage of fæces, which are the usual concomitants after the injection of morphia, and as the above symptoms of excitement did not subside in the course of about half an hour, chloroform and ether were administered for the purpose of the operation.

There have been several cases recorded of morphia producing unorthodox results, chiefly excitement, but in the above case the symptoms were well marked, amounting almost to delirium.

## POISONING BY POTASSIUM NITRATE.

A farmer noticing that one of his cows had a slight attack of mammitis, decided to administer a pound of Epsom salts. With this end in view he went to the cupboard where he was in the habit of keeping his drugs, and from a brown paper bag took a pound of what he surmised was Epsom salts. The dose was given in somewhere about a quart of warm water at seven o'clock, and the cow was not seen again until nearly one, when she was found in a dying condition. The owner, on investigating the medicine used, found that the ani-

mal had had a pound of nitre (potassium nitrate) by mistake.

Finlay Dunn says that "Moirsud reports that half-a-pound given to horses inflame the alimentary canal and urinary organs, causing depression and death usually within twenty-four hours; and Kaufman states six ounces is the toxic dose for horses and cattle."

### SPECIFIC PARAPLEGIA IN BOVINES AND EQUINES—A NEW (?) DISEASE.

By WILLIAM SCOTT, F.R.C.V.S., Bridgwater

"Many animal diseases are distinctly local in their occurrence, their incidence is confined to certain countries or districts presumably because it is only there that the factors producing them are to be found. On that account they hardly receive sufficient notice from those who practise outside their radius and never expect to have to deal with them . . . . .

"When one of those local diseases is first locally recognised as an independent pathological entity no one can say whether it is peculiar to the district in which it was first distinguished . . . . . Whoever first differentiates a disease existing in one country or district, even though it may appear at first sight to be local and due to strictly local conditions, may be on the brink of a discovery of much wider import, his duty is to publish his first clearly ascertained results to the whole profession and place others in a position to judge of their value."

The above extract is taken from an Editorial appearing in *The Veterinary Record* of March 2, 1918, and in view of the observations contained therein I am tempted to submit the following report:—

**Definition.** A specific bacterial infection affecting bovines, and occasionally equines, located principally in low lying Marsh lands, characterised by gradual systemic emaciation and pronounced atrophy of the muscular elements covering the loins and pelvis in particular, usually running a sub-acute or chronic course, and terminating in spinal effusion and paraplegia.

**History.** My first real experience of this disease dates back to the late autumn of 1917, since when I have seen 107 authentic cases. These represent a small proportion of the number of cases which have succumbed to the disease. Many were drowned in the rhines,\* many were left untreated, and many more were killed. In this neighbourhood alone I compute the financial loss sustained would reach any figure between £75,000 and £100,000—a sum, by the way, sufficient to build and handsomely endow a Veterinary Research Institute. If the disease has been in existence in this neighbourhood prior to last year I, for one, have failed to associate it with the present serious epidemic. It is reasonable, however, to point out that one may have seen in practice sporadic cases which, by reason of their limited number, cause no apprehension; and I confess it was the large proportion of cases in this outbreak that stimulated me to further investigation.

**Geographical distribution.** In my own practice the disease has shown a considerable predilection for low-lying marsh lands, situated particularly to the southern, south-western, and eastern aspect. The more western and northern areas which are somewhat hilly are, in my experience, immune. The sea-level marsh lands during the greater part of last spring and summer

were continually under water—a condition of affairs outside the memory of living inhabitants, consequently these rich pasture lands were not stocked until the late summer and early autumn, whilst the hay in some cases was not cut and carried till Christmas, and even after.

**Predisposing causes.** The two most prominent factors under this head are climatic and dietetic conditions, the latter aggravated by existing war rations—the scarcity, inferior quality, and high cost of artificial foods. In certain districts one finds from experience that land submerged even for a considerable period during the cold winter months is not only unharmed by submerging but is beneficially affected; no so, however, when flooding extends to the summer months. With thousands of acres under water—a condition which we experienced in this neighbourhood last year, the comparative stagnant condition of the water combined with the summer heat tended to excite putrefactive changes. The land became "sour," rapid decomposition of underlying vegetable matter took place, brought about by bacterial activity, and further, there was an extraordinary development of insect life, including the mosquito, in these areas. Furthermore, the summer of 1917 was extremely wet and sunless, the hay and roots, consequently, did not carry a high nutritive value, and artificial food being a scarce quantum, the normal healthy index of cattle was much reduced—50% to even 75%, making them, therefore, the more susceptible to bacterial infection.

**Etiology.** The constant symptom of paraplegia forced me to direct my operations primarily to the spinal cord, and on Nov. 29, 1917, I attempted my first *lumbar puncture* on cattle. The case was a heifer (primipara) eight months in calf. As I am not aware of lumbar puncture being a recognised procedure in veterinary practice or, indeed, if it has ever been attempted in bovines, a description of the *modus operandi* may be permissible here.

The patients being paralysed and in a recumbent position makes them easy subjects for the operation, as no methods of restraint are required. The best site for entering the spinal canal, I find, is between the fourth and fifth or fifth and sixth lumbar vertebrae, just in front of the prominence caused by the internal angle of the ilium. Having thus far located the site by careful palpation, one discerns a soft depression between the supra-spinal processes, and it is here the needle is inserted. Prior to operation the hair is shaved, the skin scrubbed with pure lysol, dried with cotton-wool and then painted with tinct. iodine. The needle having been previously boiled, is thrust through the skin immediately over the central spinal axis, the point being directed slightly forward. Considerable force is required, but as soon as the needle enters the neural canal it moves easily, and proof of this is obtained by the animal cringing, trying to move forward, and giving a groan or a bellow. The inexperienced operator may fail to locate the spinal foramen with the needle at first, in which case he must, by varying the needle angle, obtain an entrance. With practice the operation may be completed by a single direct thrust. The distance from the skin to the neural canal varies from 2½ in. to 3½ in., so that the needle must be 4 in. to 5 in. long.\*

I have made 29 lumbar operations without a single "dry" puncture, and without any untoward sequelæ. The greatest quantum of fluid removed has been 50 c.c., and the smallest 10 c.c. In by far the largest number of cases the spinal fluid *escaped under pressure*. The latter

\* A local term applied to cut ditches which fill the double purpose of intersecting fields and creating surface drainage.

\* The needle I use is similar to the one I had made for lung punctures. It is 6 in. long, bayonet pointed, and has a few perforations at its distal end.

is an important pathological fact which I desire to emphasise. In the majority of cases the fluid is quite clear, sometimes, however, it may be blood-tinged through the puncturing of a small spinal vessel. It is always strongly alkaline and rich in albumen. No post operative treatment is required. I have tapped several cases two and three times, and one case four times in all. It is well to be prepared with a sterile stillette, for one sometimes finds the needle becomes blocked with muscular and other tissue. When great difficulty is experienced in puncturing the canal, I lay the patient on her side with both hind legs drawn forward and pressed against the abdomen. By doing this the spinal column is curved, widening the supra spinatus processes and the spinal foramen.

The therapeutical value of this operation has its limitation, but in those cases where the larger quantity of fluid is removed and the greater degree of pressure apparent, the better the results appear to be. Having by these operations ascertained the constant existence of excess spinal effusion, one naturally concluded this was the cause of the disease, and some hopes of good results from its abstraction were entertained. In this I was somewhat disappointed.

After performing my seventh puncture I determined to make a bacteriological examination of the spinal fluid. By inoculating nutrient agar tubes no growth was obtained. I then flooded the media with the spinal fluid, but still no growth. On blood agar, procured by puncturing one's finger and dropping the blood into sterile citrate of soda solution and mixing it with melted agar, I secured a luxuriant growth. Having thus obtained a culture, the organism grew easily on plain agar. In every case of lumbar puncture thus made the same organism was isolated, but the process is tedious to a busy practitioner, and involves much time. I therefore felt impelled to investigate the blood stream. The hair was shaved off both aspects of the ear (apex), scrubbed with lysol, dried, painted with iodine, and the ear slit with a sterile lancet. After the blood had well washed the wound a few drops were collected in an agar tube direct, and allowed to flow evenly over the surface. Coagulation time was much deferred, a point I have noted in every case; to obtain, therefore, a fair fixation of blood elements to the agar surface it was necessary to keep the tube in a slanting position for 15 to 20 minutes. Incubating a tube thus prepared produced an excellent culture, by this means I now obtain my vaccine, which, by the way, has been for nearly every case an autogenous one. Having isolated an organism which so far was constant in its presence, efforts were made to study its characteristics. In some 12 or 15 cases additional bacteria were isolated from the blood, but their irregular characteristics and inconstant presence suggested alien and probably saprophytic origin.

As a possible factor in the etiological cycle I might mention that in every case examined—which were many—I found a louse (*Hæmatopinus tenuirostris*) infesting the patient. Lice taken from five different cases harboured a short bacillus microscopically identical with, and giving staining reactions characteristic of, the bacillus found in their hosts' blood. As a blood sucking parasite it is feasible to conclude the louse became infected from its host. On the other hand, it is just possible the louse inoculated its host with this organism at the outset. Which hypothesis is the correct one I do not pretend to say.

**Bacteriological findings.** In smears from the spinal fluid the bacilli are short, almost cocci in shape, and suggest evidences of pleomorphism. In blood smears they vary in length from 0.8 to 1.3 $\mu$ . They are rounded at the ends somewhat and possess hæmolytic action.

**Staining.** The organism stains well with the ordinary aniline dyes, but not by Gram. With carb. fuchsin some of the bacteria stain irregularly. Studied through-out the field some present bipolar staining.

**Biological characters.** It is aerobic and grows best at from 35° C. to 38° C.

**On gelatine (surface),** growth is very tardy, the colonies being white with irregular edges; (*stab*), on the surface a delicate white slime; along the course of the needle a faint, regular, nail-like growth occurs. The gelatine does not liquify.

**Agar (plain).** One very seldom obtains a growth.

**Agar (blood).** Growth luxuriant in twelve hours: the colonies tend to coalesce, covering the whole surface with a grey, glistening, toughened surface mass.

**Glucose agar (surface).** Similar to blood or serum agar; (*stab*), extensive surface growth; along the course of the needle filiform growth.

**Glycerine agar (surface).** Colonies more discrete than in the preceding media, lighter in colour and not corrugated. (*Stab*), surface growth, rich and extensive, along the course of the needle, echinate.

**Litmus agar.** Moderate colonies of light grey, with irregular borders.

**Broth.** A grey surface scum forms in 24 to 36 hours, but the medium does not become cloudy.

**Potato.** No growth. On alkaline potato a slimy grey growth occurs.

**Acid.** None.

**Gas.** None.

**Motility.** Non-motile.

**Vitality.** Colonies exposed to day-light on nutrient media live for three months at least.

[NOTE.—Considering paraplegia is the most important symptom and condition in this disease, the bacillus associated with it might be known as the "*Bacillus paraplegicus*."] ]

**Semelology.** When the veterinarian is called in he usually finds his patient down and unable to stand. Attempts to make her rise generally succeed in getting her to raise the front parts, making her take the position of a dog sitting on its haunches. The pulse is slightly quickened and is often dicrotic, the respirations normal, and the temperature only slightly raised. The appetite, save in extreme cases, is usually good throughout and occasionally capacious, the bowels are normal unless complications such as Johne's disease or distomatosis exist. Singularly enough, in all cases of uncomplicated paraplegia the coat is glossy and healthy-looking, and the skin is not hidebound. In a wasting disease such as this, this phenomena, in my experience, is unique, and it is so palpable in every case as to be most striking. The eye carries its natural brightness almost to the end. The conjunctiva is normal in appearance save that part of the mucosæ which protrudes as a bulb at the minor canthus when the eyelids are parted and the membrana nictitans extends over the eyeball. This part is in nearly every instance of a tinge between lemon and orange, and appears as a striking contrast to the colour of the rest of the mucosæ.

When such an animal goes down she is quite incapable of rising until the elapse of many days and even weeks. The muscles covering the lumbar and pelvic regions seem almost to disappear, giving these areas a skeletal appearance, which is particularly noticeable when one stands and looks along the line of the back. Such an observation compels one to look upon the subject as a "screw," but if looked at sidewise, the ribs being usually well covered and the abdominal viscera well filled, the contrast is very great, and one's opinion is likely to be revised. This disparity is most constant and pronounced save in extreme and complicated cases, so much so, in fact, that by intuition I have gone through dairies pick-

Heifer after being paralysed for five weeks.  
Note wasted pelvic region.

ing out infected cases for immunisation purposes, and these have generally been confirmed later by bacteriological tests. This muscular atrophy, I incline to opine, is due to neurotrophic influences. The usual history one receives is that the cow was found in a rhine, she was dragged out, but was unable to stand, the natural inference being that getting into the rhine was the cause of her inability to stand rather than a case of *post hoc propter hoc*.

By far the larger number of cases are in calf cows, between the 8th and 9th month of pregnancy, in fact just at the period when the foetal requirements are most exacting upon the maternal resources while the gravid uterus is at its heaviest.

It will be patent that the affection in such conditions has a double economic import, inasmuch as the offspring cannot be strong and healthy; while parturient complications are likely to supervene. Among the most common met with are abortion, premature delivery, and a sickly calf, prolapsed uterus, permanent paraplegia. The paralysis is motory rather than sensory, the reflexes of the limbs appearing to be quite normal.

In the four cases met with in equines, one was a gelding and the other three were pregnant mares. The two cardinal symptoms in them, as in cattle, were in evidence—characteristic atrophy of certain sets of muscles, and paraplegia. The horse in this, as in all other forms of paraplegia, is not such an amenable patient as the ox. When he is unable to stand, as everyone knows, he rolls on to his side, fights with the air and hastens by exhaustion, dissolution.

**Treatment.** Ordinary therapy has no specific effect upon this disease, but withal I do not advocate its entire elimination. The excretory organs, as in all bacterial intoxications must be kept flushed by such agents as sodii chlor. and mag. sulph. for the bowels, turpentine for the kidneys, and salicylic acid for the skin. General management must be carefully attended to in its min-

utest detail. Thus, when the animal is down one must recognise the fact that as it will remain in the recumbent position many days, efforts must therefore be directed against bed-sores,\* the *bête noir* in these cases, by making provision for the animal to lie on a soft floor. One or two feet of sand or gravel soil makes an excellent ground-work, covered with short, soft bedding. The patient should be turned two or three times a day, and, if need be, pads may be put on the knees and hocks. Averse as I am to slinging in cattle practice generally, I have seen the greatest benefit derived by daily placing the patient in slings for one to two hours at a time. By so doing the risk of muscular cramp and bed-sores is considerably reduced.

**Special treatment.** In my early lumbar puncture cases I carried out a series of direct injections on to the spine, but the results were so far disappointing. These remedies consisted of warm solutions of (a) strychnine, (b) neo salvarsan, (c) tinct. iodine, and eventually I gave them up. After detecting the bacillus in the blood stream, I set about preparing autogenous vaccines. The net results obtained from these were, (i) the fourth injection cleared the blood stream of the bacillus in several cases, so that no artificial cultures could be obtained. In obstinate cases six injections were required. (ii) In uncomplicated cases the course of the disease, I believe, was shortened. The largest percentage of failures were those cases showing complications. The cases which were taken early, that is to say, before they went down, responded most readily to vaccination, two injections served to clear the blood stream, and only very occasionally three were required; and the rapidity with which these cases improved in condition afterwards is worth noting. After many experiments, speaking generally, the following standard of doses gave me the best results:—

First dose	Sterile	...	10,000,000,000
Second dose	Sterile	...	30,000,000,000
Third dose	Very attenuated	...	60,000,000,000
Fourth dose	Slightly attenuated	...	60,000,000,000
Fifth dose	Attenuated	...	60,000,000,000
Sixth dose	Virulent	...	30,000,000,000

One dose to be injected every five or six days.

In addition to vaccination, sodium cacolyatet† was injected two or three days after each vaccine injection, in five cases with, I think, decided benefit, for recovery appeared to be more rapid than when the vaccine was used alone. The dose of this drug to begin with was one gm., doubled at each injection; the maximum dose being four gm.

TABLE SHOWING MONTHLY TOTAL OF PARAPLEGIA CASES AND TREATMENT ADOPTED.

	No. of cases.	Destyd.	Died.	Recovered.
Nov.	12	5	4	3
Dec.	10	3	2	5
Jan.	15	7	4	4
Feb.	23	6	7	10
Mar.	30	3	13	14
April	15	...	6	9
May	2	...	...	2
Total	107	24	36	47 †

\* It reflects no credit upon the practitioner to cure his patient of paraplegia and eventually allow it to die from septicæmia, the result of neglected pressure sores.

† Sodium cacolyate (sodium dimethylarsinate) is an organic compound of arsenic, and is less toxic and more tolerant than the inorganic combination. I am greatly indebted to Messrs. Parke, Davis & Co. for preparing, at my request, this drug, and supplying me with a liberal quantity for investigation purposes.

†*Treatment.* Nov: Ordinary, 3. Dec: Ordinary, 2; Vaccine, 3. Jan: Vaccine, 4. Feb: Vaccine, 10. Mar: Vaccine, 14. Apl: Vaccine, 6; Vaccine *cum* Sodium cacodylate (subcut.), 3. May: Vaccine *cum* Sodium cacodylate (subcut.) 2.

**Prophylaxis.** When practicable, cattle should be moved from marsh land to high, dry ground. The hay from such ground should be used sparingly and mixed with salt and given along with high-ground, *hard* hay. Cattle that are losing in condition and are showing symptoms of muscular atrophy should be isolated from the herd and a *biological* examination of the blood made—microscopical examination of a blood smear

giving *negative* results is *no proof* that the organism is absent.

Cattle harbouring the bacillus should be isolated from the healthy, vaccinated with preferably *autogenous* vaccine and fed on the most nutritious food obtainable. In those herds where the disease has shown itself I strongly advise immunising them all by vaccination. In the case of 33 cows which were found to be infected with the bacillus although clinically only lightly affected, I carried out immunisation with apparent good results by giving the invariable initial sterile dose of 50,000,000,000, and a second attenuated dose of the same strength ten days later. Two out of this number went down; one died, the other lived, while the remaining 31 did well.

CHART SHOWING MONTHLY RETURN OF PARAPLEGIA CASES.

A B C (A) No. of cases each month: (B) Recovered: (C) Destroyed or died.

**Morbid anatomy.** The blood is very thin and watery. The serous membranes—cardial, pleural, peritoneal (parietal and visceral), and spinal—are all soaked with non-coagulated serum, while the serous cavities contain to a greater or lesser degree an accumulation of serous fluid which is very alkaline and rich in albumen. Occasionally the mucous membranes are similarly affected; but the connective tissues seldom. In other words, serous effusions appear in those tissues whose anatomical dispositions offer the blood vessels the least support in free surfaces and as the effusion is non-inflammatory one may presume that some specific action is going on, not only in the capillary vessel walls but also in the blood itself, by free bacterial toxins and probably by the bacteria themselves. The muscular elements are pale and flabby, while those in the region of the loins and quarters are almost grey in colour and soapy to the touch. In uncomplicated cases the macroscopic appearances of the parenchyma of the various organs do not suggest anything abnormal.

**Compendium.** I have endeavoured to show: (1) That if this disease is not new in the annals of veterinary science it never has previously reached the serious proportions it has in the years 1917-1918; nor are there any records, so far as I am able to trace, of it having been previously described.

(2) That a special bacterium always accompanies the condition, its constant presence having been demonstrated not only in the general circulation, but also in the spinal effusions.

(3) That this effusion is always in excess, and on tapping leaves the canal *under pressure*.

(4) That two out of the three most important postulates of Koch have been fulfilled in associating this organism with the disease; while in addition to these, vaccines derived from the bacterium in question certainly exercise a specific action upon the patients, with considerable curative and prophylactic values.

(5) That vaccination offers to stockowners an important economic proposition, particularly considering the face value of horses and cattle to-day.

#### Koch's Postulates.

(i) The organism in question must be present in the tissues, fluids or organs of the animal affected with or dead from the disease.

(ii) The organism must be isolated, and cultivated outside the body on suitable media for successive generations.

(iii) The isolated and cultivated organism, on inoculation into a suitable animal should reproduce the disease, and the same organism must be again obtained from the inoculated animal.

## ABSTRACTS FROM FOREIGN JOURNALS.

EQUINE TRYPANOSOMIASIS IN MOROCCO—  
INFECTION OF A MILK-SUCKING PUP.

H. Velu and R. Eyraud, in an article upon this subject refer to the works of Nattan-Larrier and Lanfranchi on the excretion of trypanosomes by means of the milk of infected females (*Bull. Soc. Path. Exot.*) The following case is recorded:—

Five days after giving birth to three pups a bitch was infected subcutaneously with 20 c.c. of the blood of a goat infected with the trypanosome affecting horses in Morocco. A rise of temperature took place on the third day after injection, and a few parasites appeared in the peripheral blood on the 14th day; they then disappeared, but became very numerous again about a month afterwards, and then again for about 15 days before the animal's death, which took place on the 66th day after injection.

One pup was allowed to suck its mother, while the other two were taken away 14 days after birth; these two grew up normally. The first, when about two months old, seemed to have become stunted in growth and dull, and then gradually became more and more emaciated. When three months old it became affected with conjunctivitis and then keratitis of the right eye. On examination of the blood a few days afterwards, a few trypanosomes were found, which became more and more numerous till the animal's death at the age of three and a half months.—(*Trop. Vet. Bulletin*).

THE ACTION OF THE PITUITARY GLAND  
UPON THE RENAL FUNCTIONS.

M. Romme has given an account of the researches of different workers upon this subject in *La Presse Medicale* for 1917.

In 1901, Magnus and Schäfer published their work upon the diuretic action of the pituitary gland. In 1906 Schäfer continued his experiments in collaboration with Herring, and came to the conclusion that this diuretic action is dependent upon the secretions of the posterior lobule and the *pars intermedia* of the gland, extracts of which were considered by these two workers to be the physiological diuretic *par excellence*. They found, also, that the anterior lobule of the gland was destitute of all diuretic action. In consequence of these experiments, the primary rôle in the genesis of diabetes insipidus was attributed to a hyper-function of the pituitary gland.

But the conclusions of Schäfer and his collaborators, admitted by the classical authors and reproduced in many works, have not been confirmed by all the later researches, many of which arrive at distinctly contradictory conclusions.

The clinical experiences published in 1916 by Motzfeldt, who had already repeatedly studied the relations between the pituitary gland and the kidney, appear to demonstrate incontestably that the posterior lobule of the gland exercises a real action upon the kidney, but, contrary to the currently admitted conclusions, produces diminution of diu-

esis and urinary concentration. This conclusion is in accord with the results obtained by Lereboullet and Faure-Beaulieu in the treatment of a case of diabetes insipidus with pituitary gland.

The mechanism of this action is obscure. Does the pituitary gland act upon the kidneys by the circulatory system, by the automatic or sympathetic nervous system, or by the intervention of another gland of internal secretion? The problems cannot yet be discussed. It may, however, be pointed out Frankl-Hochwart and Fröhlich have demonstrated, in an animal under the influence of injections of pituitrin, indisputable signs of hyper-sensibility both of the automatic and sympathetic nervous system in equal degree.—(*Revista de Higiene y Sanidad Pecuarias*). W. R. C.

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

E. J. Burndred, Capt. A.V.C.	£1	1	0
Archibald Edgar, Withorn	1	1	0
Daniel Hamilton, Hamilton	1	1	0
Charles Nicholson, Capt. A.V.C.	1	1	0
D. Pugh, Sevenoaks	1	1	0
James E. Syme, Capt., A.V.C.			
(1915-16-17-18)	4	4	0
Frank S. Warburton, Capt. A.V.C.	1	1	0
A. E. Willett, Capt. A.V.C.	1	1	0
F. W. Willett, Staines	1	1	0
Previously acknowledged	876	18	5

## ARMY VETERINARY SERVICE

Buckingham Palace, June 29.

The King held an investiture in the Quadrangle of the Palace this morning.

The following were introduced into the presence of His Majesty, when The King invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted:—

## THE DISTINGUISHED SERVICE ORDER.

Lieut.-Colonel Charles Edgett, Canadian A.V.C.  
Lieut.-Colonel David Tamblin, Canadian A.V.C.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, June 27.

## REGULAR FORCES. ARMY VETERINARY CORPS.

Capt. A. L. Horner to be actg. Maj. whilst empld as Asst. Dir. of Vety. Servs. (Aug. 29, 1916), and to retain his actg. rank on appt. as Dep. Asst. Dir. of Vety. Servs. (June 16, 1917).

June 28.

Capt. P. J. Simpson D.S.O. (T.F.), relinquishes the actg. rank of Lt.-Col. on ceasing to hold the appt. Asst. Dir. of Vety. Servs. (June 7).

Capt. E. G. Turner, D.S.O., relinquishes the actg. rank of Maj. on ceasing to hold the appt. of Asst. Dir. of Vety. Servs. (Apr. 8).

June 29.

Maj. (Bt. Lt.-Col.) J. J. Aitken, D.S.O., relinquishes the actg. rank of Lieut.-Col. on ceasing to be specially empld. (May 6).

July 1.

Temp. Lt. to be temp. Capt. :—M. M. McLeod (Dec. 28, 1917).

Temp. Capt. M. M. McLeod relinquishes his commn. on account of ill-health contracted on active service, and is granted the hon. rank of Capt. (July 2).

To be temp. Lt. :—A. McTurk (June 12).

TERRITORIAL FORCE, ARMY VETERINARY CORPS.

July 3.

Capt. (actg. Maj.) J. A. Dixon relinquishes the acting rank of Maj. on ceasing to commd. a Vety. Hospital (June 18).

### VETERINARY SURGEONS AND NATIONAL SERVICE.

To the Editor of "The Veterinary Record."

Royal Veterinary College,  
Camden Town, N.W. 1, June 26.

Sir.—I enclose the following correspondence which may be of interest to many of your readers who may have noted the action of the Central Veterinary Society in the above matter.

I am taking the unusual course of sending it to you now, since it would otherwise be delayed for about a month for the publication of the proceedings of the next meeting of the Central Veterinary Society.

Yours faithfully,

GEO. H. WOOLDRIDGE.

Copy.

Central Veterinary Society,  
10 Red Lion Square, W.C. 1.  
7th May, 1918.

To the Rt. Hon. the Minister of National Service.

Rt. Hon. Sir,—I have been requested to forward to you the following Resolution passed at a meeting of the Central Veterinary Society on the 2nd inst., and to beg that you will give it your very favourable consideration :—

That this Central Veterinary Society is of opinion that the cases of Veterinary Surgeons of military age should be referred to a Central Panel, composed of Veterinary Surgeons, who would act as an Advisory Committee to the Ministry as in the case of medical practitioners, and that their decision should be accepted by the Tribunal.

With regard to a panel, the Society would suggest the President and Council of the Royal College of Veterinary Surgeons, or, failing that, the National Veterinary Medical Association of Great Britain and Ireland.—I am, Rt. Hon. Sir, yours obediently,

G. H. WOOLDRIDGE, President.

Copy.

Ministry of National Service,  
Westminster, S.W. 1.  
May 23, 1918.

Sir,—I am instructed by the Minister of National Service to advert to your letter of the 7th inst. The suggestion that a special advisory committee should be appointed to deal with applications to Tribunals on behalf of Veterinary Surgeons has been considered, but Sir Auckland Geddes regrets that he is not able to assent to the proposal.—I am, Sir,

Your obedient Servant,

(Signed) H. R. BOYD.

The President, Central Veterinary Society.

### VETERINARY STUDENTS AND ARMY SERVICE.

Dear Sir,—As a veterinary student I consider it my duty to draw the attention of your readers to the way in which we are being treated as regards military service. Some few months back a special effort was made to get as many third and fourth year students released from the army, and other positions in which they were, in order that they might complete their qualifications.

Among others I myself have returned in order that when qualified I might join the A.V.C.; now we are given to understand that all students of Grade I and II, between the ages of 18 and 23, are to join up, and apparently not in their own corps. It seems to me a disgraceful thing that men who have gone to considerable expense to obtain their qualification should not have their knowledge better applied.

At the beginning of the war a groom could join the A.V.C. as a Quarter-master-sergeant, but apparently "the powers that be" do not consider a veterinary student of three or four years standing capable of undertaking similar work, although he has attended courses in Materia medica and the study of disease, and in many cases managed veterinary practices. It seems to me only fair that we should have some recognition of our capabilities, and if it is really necessary that we should be taken from our studies, I think I am safe in saying that the number of men that will be obtained from all the colleges concerned will not exceed 100, it would not be asking too much that we should be made Second Lieutenants in the A.V.C., and attached to Veterinary Hospitals where we should be, in the first place, of greater service to our country, and, secondly, gain surgical experience which would be of great advantage to us and the public generally when we have obtained our diploma and launch out into whatever branch of the profession we decide to adopt. I feel confident that unless something of the kind is done very few of us will return after the war. I might add, this calling up notice does not affect me, but if we are not given a clearer understanding of our position with regard to this matter, I, for one, shall not wait to be fetched.

I trust this matter will be taken up through the right channel.

LOOKING AHEAD.

### OBITUARY.

ARTHUR RICHARD ROUTLEDGE, F.R.C.V.S., Louth, Lincs.  
Graduated, Edin: May, 1895.

Capt. Routledge, who was 44 years of age, had been discharged from the Army on account of an injury received from the kick of a mule, resumed his veterinary practice, and had been elected a member of the Town Council. Unfortunately he became seriously ill before he was able to take his seat, and died in the 4th Northern General Hospital, Lincoln, on June 27th.

The Military funeral took place at Louth on Monday. The former portion of the service was held in the Parish Church, and was attended by the Mayor and Corporation, magistrates, and farmers of the locality, as well as representatives of the military authorities.

GEORGE FRED. ROSE VINCENT, M.R.C.V.S., Sutton, Surrey.  
Graduated, Lond: April, 1868.

Mr Vincent died 24th June, aged 71.

HENRY SMITH, M.R.C.V.S., Worthing.

Graduated, Lond: July, 1884.

Mr. Henry Smith, one of the best-known veterinary surgeons in West Sussex, passed away at his residence, Winton Lodge, Worthing, on Thursday, June 27th.

The deceased, who was fifty-six years of age, had been in failing health for some months; but the news of his

death nevertheless came as a painful shock to his many friends.

Son of the late Dr. Samuel Smith, of Winchcombe, Glos., the deceased was educated at Cheltenham Grammar School, and obtained his diploma R.C.V.S. in 1884.

He came to Worthing in 1886, where he purchased the old-established practice of Messrs. Rolls & Tyler, originally founded here by Mr. Coomber more than a century ago.

In the early part of 1900 Mr. Smith was appointed Veterinary Inspector for this Division under the County Council; and for several years past also held a similar appointment under the Town Council.

A great lover of animals, and especially of horses, he took an active part in the organisation and management of the old West Sussex Horse Show and Jumping and Driving Competition in Beech House Park, which used to be such a prominent feature of the season's attractions at Worthing; and he was actively associated with the several Dog Shows that have been held in the town.

In March, 1909, he was unanimously chosen President of the Southern Counties Veterinary Society, with the late Mr. J. A. Todd as its Hon. Sec.; and in the summer of that year his fellow members held their periodical meeting at Worthing, when Mr. Smith entertained them to dinner at the Albion Hotel, and afterwards continued his hospitality at his residence in Chapel Road.

His wide professional knowledge, coupled with a genial disposition, gained him many friends, and the news of his death will be received with general regret, not only by his own clients and professional colleagues, but by a wide circle of acquaintances.

A widow, three daughters, and two sons are left to mourn his loss. One of his sons is at present in practice as a veterinary surgeon at Horsham; the other holds a commission as Lieutenant in one of the Battalions of the Royal Sussex Regiment.

The interment took place on Tuesday afternoon, at Broadwater Cemetery, preceded by a service at Christ Church. A wreath from the President and members of Southern Counties Veterinary Society was among the many floral tributes.—*Worthing Gazette*.

### Personal.

FOSTER—NOWILL. On June 26, at St. Bartholomew's Church, Sydenham, by Rev. W. H. Boyne Bunting, Vicar, assisted by Rev. R. Bevan Jones, Vicar of St. Augustine's, Bermondsey, Major Arthur Norman Foster,

A.V.C., younger son of Mr. and Mrs. Philip Foster, of Clifton, Derbyshire, to Mary Dorothy, only daughter of Mr. Ernest Nowill and the late Mrs. Nowill, of "Kirk lynton," Sydenham, S.E.

Mr. W. H. JEBSON, V.S., Pocklington, has purchased from Mr. Edwin Pears, Laytham Green, at a good price, two of his Hackney ponies, a two-year-old filly and a yearling entire colt. Both are by Melbourne Spot, who made 450 gs. at the late Mr. Cliff's sale. Their dam, Lady Moon, is a 13 h. 2 in pony by Champion Successful, and their granddam Mignonette by Champion Berkeley Model.

### Seaweed as a food.

The following notes are from the correspondence columns of *The Scottish Farmer* :—

"The Rev. J. G. Wood in his well-known book, 'Common Objects of the Sea-shore,' mentions 'fucus serratus' as being most useful for feeding cattle. On this West coast a band of it grows all along the shore, about 30 yards in width, and it grows nearer to the land than any other seaweed, only being covered by the sea at high-water. Consequently it is much less salt to the taste than most seaweed. It looks rather like carajeen. I boil it and feed both hens and pigs on it, mixed with boiled potatoes. The pigs are especially fond of it, and thrive well on it. When boiled it becomes dark brown, and has an almost 'meaty' smell. This seaweed never dies down. Here the sheep and wild goats eat it when grass is scarce, and I have never heard of it harming them. I am told that in olden times it was much used in the Highlands as feeding for pigs. It is a pity that it is not more used."

"I had a farm on the sea coast for 29 years, and sheep suffered no harm from eating seaweed.—M.C."

### ANGLO-FRANCO-BELGIAN VETERINARY RELIEF FUND.

JULY 13, 1918.

VOL. XXXI.

## THE COUNCIL MEETINGS.

The Councilmen attended in good numbers last week, and consequently the important arrears of Registration Committee work could be cleared up. It is to be hoped that this is an augury of better attended meetings in future.

The unanimous re-election of the President will please everybody. The course was obviously the wisest. No other man, just now, is quite so well fitted for the Presidential duties as Mr. Garnett; and the whole profession will feel confident that everything possible will be done for our interests throughout the coming year.

Our finances show a little improvement, but the position remains essentially the same. Voluntary subscription must continue, and must increase in future, or the work of the College cannot go on.

The negotiations with the Government regarding the re-settlement of veterinary officers in civil life should be closely watched. Not much can be said concerning them at present; but they may profoundly affect the future of the profession. The movement for financially assisting veterinary students who have served in the war may also prove of great importance.

The endeavours to prevent the calling up of Veterinary Students have not been successful. This is damaging to the profession, and mischievous to the prospects of agriculture. The evil fruits will soon be in evidence, and will be with us for years to come. The efforts to establish a Veterinary Tribunal have likewise suffered reverse—for reason given see report. But this is not yet considered hopeless.

A matter of direct importance to practitioners—the supply of Turpentine for medicinal purposes—has been set straight by the action of Mr. Bullock (pp. 13-14). The President calls the attention of members to this information. Too much of the time of the Secretary is taken up in replies to needless questions—needless because the information asked for has been published for the use of the members, and should be kept for reference. Sir S. Stockman makes the same complaint for the Board's staff—they "are inundated with questions." It is weary work trying to help those who will not help themselves.

Two other items occur in the report of the Parliamentary Committee. The definition given in several official notices in South Africa (Nov. 10, p. 191)—"Veterinary Surgeon" shall mean and include the G.V. Surgeon or Inspector of Stock or if no such appointment has been made, the magistrate"—has been cancelled. And a draft of the V.S. Bill for S. Africa has been referred to a small but effective Committee to draft a report and suggested reply.

## POISONING BY ACACIA LEAVES IN HORSES.

Scholz observed numerous cases of poisoning, which were afterwards proved to be due to the ingestion of acacia leaves, in the horses of an ammunition column operating in Roumania. The animals were being fed upon a mixture of oats, bran, and maize.

The first case was a horse which, immediately after returning from the firing line, showed very serious colic. He threw himself upon the ground, and had cold sweats. The temperature was 98.2° F.; the pulse was 80, and scarcely perceptible. Despite treatment by caffeine and rubbing, the animal died in convulsions.

The same morning, two heavy Belgian horses became ill. One, the second animal in the series of cases, stood with the limbs apart, the head low, the eyes half-closed, and covered with sweat. As the surrounding temperature was 100.5° F. in the shade, the case was diagnosed as heat stroke. Cold packs were applied upon the head and the whole body, and caffeine was administered. This treatment was followed by a transient improvement; but after five hours the horse became so much worse that slaughter was decided upon.

The second Belgian horse was very agitated, and passed small quantities of normal faeces at short intervals. Rectal exploration showed that some parts of the intestine were full. Palpation of the abdomen revealed pain. Morphine was administered, and hot packs were applied. This treatment seemed to be efficacious; for the animal became calm, and recovered in a few days.

At the same time, notice was received of a fourth case. A horse, while returning from the firing line, became affected with symptoms similar to those of the first case. This animal threw himself to the ground, where he died after a brief death-agony.

Three other cases occurred during the afternoon. In one—the fifth case—symptoms like those of the first and second cases were seen, with the addition of great restlessness. The sixth and seventh cases had very pronounced lumbar pains, but recovered quickly; while the fifth case died during the night.

In the same night a grave case of colic appeared in a saddle horse. This eighth case was treated with morphine, arcoline, etc., but, notwithstanding an apparent improvement, died the next morning.

The first, fourth, fifth, and eighth cases all showed the same post-mortem appearances—viz., intestinal inflammation, parenchymatous degeneration of the liver, kidneys, and heart, hyperæmia of the lung, and slight swelling of the spleen. These lesions, together with the symptoms presented, caused

forage poisoning to be thought very probable. At first it was thought that the bran might be the cause; but this hypothesis was quickly discarded, as there had been no change in the supply, and no trouble had been seen in the other animals whose food was provided from the same source. It then became known that cases of poisoning by acacia leaves had previously occurred in the locality where the column was staying. As the intestines of the fifth and eighth cases were not yet destroyed, their contents were examined, and it was found that the dense faecal mass contained numerous fine stems, partially ligneous, and also some acacia leaves still intact. Upon re-examining the histories of the cases, it was proved that the cases of poisoning were verified exclusively in horses which had been tied to acacia trunks or near acacias, while no trouble had occurred in those which had bivouacked under fruit trees or in the open country. From that time forward the attention of the men was drawn to the toxicity of acacia leaves, and the horses were prevented from eating them; and no more cases of poisoning occurred.—*La Clinica Veterinaria*.

#### THE APPARENT CLOSURE OF THE CERVIX UTERI IN CERVICITIS.

Prof. W. L. Williams, during the clinical demonstration upon sterile cows which followed his paper on Contagious Abortion before the American V.M.A. last August (*vide V.R.*, Dec. 29, 1917, page 260), made some remarks upon this subjects. Formerly veterinarians talked much of the "closure of the os uteri," or "closure of the womb;" but Williams considers that atresia of the cervical canal in cows is essentially fiction. As a congenital condition it exists rarely, along with the general arrest in the sexual development. Speaking generally, the cervical canal is open and passable; but penetration is rendered more or less difficult by the anatomical arrangement of the cervix. The difficulty is further and greatly intensified by disease. The circular folds of the cervical mucosa with their margins directed outwards, towards the vagina, cause the catheter or sound to be deflected and lodged in a *cul de sac* behind the folds, instead of following the cervical canal, which perhaps bends abruptly in some direction. In cervicitis (and when metritis is marked, the pus passing out through the cervical canal inevitably causes cervicitis) the bases of the circular folds become enlarged and sclerotic. The sclerotic mass pushes from one side and bends the cervical canal out of a straight line, sometimes as much as two inches. The veterinarian who is ignorant of these facts concludes that the canal is "closed," erroneously thinks that force is justified and demanded, and applies it with disastrous results. In mentioning the matter, Williams emphasised the grave danger of undertaking modern veterinary obstetrics without sufficient study of its details.—(*Journal of the American V.M.A.*)

W. R. C.

## Royal College of Veterinary Surgeons.

### MEETING OF COUNCIL.

A meeting of the Council was held at the College, 10 Red Lion Square, London, W.C., on Friday, July 5th. Present: Mr. F. W. GARNETT, C.B.E., J.P., President, in the Chair; Sir John M'Fadyean, Maj.-Gen. Blenkinsop, D.S.O.; Maj.-Gen. Thomson, C.B.; Messrs. J. Abson, Banham, Barrett, Carter, Coleman, Dunstan, Gaiger, Howard, Lawson, McCall, McKinna, Mulvey, Packman, Share-Jones, Slocock; Sir Stewart Stockman; Messrs. Sumner, Trigger, Wharam, Wilson; Mr. G. Thatcher, Solicitor; Mr. F. Bullock, Secretary.

*Minutes.* The minutes of the previous meeting of Council, on July 6th, 1917, having been printed and circulated, were taken as read, and confirmed.

### ELECTION OF OFFICERS.

*President.* Sir J. M'FADYEAN: I rise with a sense of duty, but also with pleasure, to move that we elect Mr. Garnett to the Presidential chair for the ensuing year. It may have occurred to some of you that special arguments ought to be adduced to justify a proposition that any member of the Council should be elected for the fifth time to fill the Presidential chair. There is no difficulty in finding special reasons for such a course, because we live in highly exceptional times. In pre-war times the duties of the President of the College were far less onerous than they are at the present time, when matters of the very greatest importance to the welfare of the profession in connection with the conduct of the war and what is called the period of reconstruction after the war, are constantly arising. I venture to say that there is no member of this Council who has these matters at his finger ends as has our President. This is not a case of conferring an honour on Mr. Garnett. I therefore propose that he be re-elected because I am perfectly satisfied that he cannot be changed without detriment to the interests of the profession at the present time.

Mr. R. C. TRIGGER: As one of the senior members of Council, I have very great pleasure in seconding the nomination of Mr. Garnett for the Presidential chair. I quite agree with the proposer that this is in no sense conferring a compliment on Mr. Garnett. We are asking a very great favour of him in asking him to give us his valuable time and services, considering the unmeasured strength he has been to us during the past year. He has guided the ship during the past few years and he has taken us through very difficult times in a manner which could not have been surpassed by any other member of the Council. I have had the privilege of sitting on the Council for 28 years, and it has been my pleasure to sit under Mr. Garnett during the last few years, and I venture to say that never in all these years has the business of the Council been conducted in a better or more able or more efficient manner, and that in the most strenuous times, and I think the least we can do is to ask the Council to re-elect Mr. Garnett, and at the same time to thank him for the great services he has rendered us. I have very great pleasure in seconding the nomination.

Mr. J. H. CARTER: I wish to support that proposal, and I ask those in favour of the motion to hold up one hand.

The motion was carried unanimously.

The PRESIDENT: Sir John M'Fadyean and gentlemen, the present, perhaps, is the proudest moment of my life, to think that I have retained your confidence for a period of five years, and you have elected me for another

period of work. I can only thank you most heartily and I trust, with your help, that I may be able to carry out during the coming year the work that will fall upon me.

*Vice-Presidents.* Dr. J. McI. McCall and Mr. J. McKinna were unanimously re-elected Vice-Presidents.

*Treasurer.* The PRESIDENT: I do not think I need mention who our Treasurer is or who is going to be our future Treasurer, because I feel it is the unanimous wish of all to re-elect our present one, Mr. Mulvey. I hope he may live long to occupy that position.

The motion was unanimously agreed to.

*Secretary and Registrar.* On the motion of the President, Mr. Fred Bullock was unanimously re-elected Secretary and Registrar.

The meeting then terminated.

#### QUARTERLY MEETING OF COUNCIL.

A quarterly meeting of Council was held immediately following the ordinary meeting. Mr. Garnet, President, occupied the chair, and the same members were present at the other meeting.

*Minutes.* The minutes of the previous meeting of Council having been printed and circulated, were taken as read, and confirmed.

*Apologies for absence.* The SECRETARY announced that apologies for absence had been received from the following members: Mr. J. W. Brittlebank, Dr. O. C. Bradley, Mr. J. Clarkson, and Mr. T. S. Price.

*Obituary.* The SECRETARY read the Obituary list.

*Correspondence.* There was no correspondence.

*Right of way.* The SECRETARY announced that, in accordance with custom, he passed through the College building into Yorkshire Grey Yard on June 22, and on several other occasions during the year to maintain the right of way of the College through the yard.

#### REGISTRATION COMMITTEE.

The following report of the meeting of the Registration Committee, held on Thursday, July 4, was read and adopted:—

An application for restoration to the Register was received from Mr. L. Crook (a member whose name had been removed under Section 6), accompanied by testimonials. It was resolved to recommend that, subject to confirmation from the officer in charge of Records A.V.C. as to this member's conduct while in the Army Veterinary Corps, that his name be restored to the Register of Veterinary Surgeons.

The President reported that Mr. Sewell's appeal against the decision of the Council in the removal of his name from the Register had been dismissed by the Privy Council. Further complaints were received, but it was resolved that no action be taken for the present.

Nine other cases were considered by the Committee. Two were adjourned for further evidence; in another, an undertaking was received; in a fourth, it was reported that the offence complained of had been discontinued; and in the case of a non-member using title, it was resolved to recommend that a prosecution be instituted if sufficient evidence was available.

The Solicitor reported that Mr. J. R. Welsby, member, had been convicted of a felony and sentenced to twelve months imprisonment with hard labour. It was resolved that Mr. Welsby be called to attend the meeting of the Committee in April, 1919, to show cause why his name should not be removed from the Register.

Correspondence was submitted, and the Secretary was instructed as to the replies to be sent.

The SECRETARY announced that, since the meeting of the Committee, he had received a letter from General Blenkinsop, who said he had enquired as to the character of Mr. L. Crook and found it was very good.

On the motion of the President, the names of D. Sinclair, W. Gardner, B. M. Gunn, and L. Crook were restored to the Register; and, on the motion of the President, the name of W. J. Moran was removed from the Register.

Authority was given for the Seal of the College to be affixed to two prosecutions, if the Solicitor was satisfied with the evidence brought forward.

#### FINANCE COMMITTEE.

The following report of the meeting held on Friday, July 5th, was read and adopted:—

*Financial Statement.* The Treasurer submitted his financial statement for the quarter, showing a balance in hand of £156 16s. 5d., and liabilities amounting to £220 15s. 5d.

It was resolved: That the financial statement be adopted, and that the Treasurer be ordered to pay the liabilities shown, together with cheques for monthly salaries, Examination expenses, gas, electric light, and petty cash.

*Appointment of Clerk.* The Treasurer reported that he had interviewed several applicants for the vacant clerkship, and had appointed Miss K. C. Blake at a salary of 45/- per week.

It was resolved: That the appointment of Miss Blake at the salary named be approved, and that Mr. Mulvey be thanked for the trouble he had taken in the matter.

*Voluntary subscriptions.* The Secretary reported that the sum of £198 16s. 5d. had been received during the quarter in voluntary subscriptions.

*Auditors' fee.* An application was received from the Auditors for an increase of fee.

It was resolved: That the Auditors' fee be increased to sixteen guineas per annum, this amount to be an inclusive fee.

*Adjoining site.* A report was received from the Solicitor with regard to the condition of the adjoining site and building.

It was resolved: That no further action be taken.

Mr. W. J. MULVEY: The financial statement this time is somewhat more favourable to us on the face of it. It shows a balance in hand of £156, but we have to set against that certain payments which will be made before the next meeting of the Council which will clear off the balance that we now hold. I want first of all to say how much the Council appreciate—and I am sure they do—the way in which the individual members of the profession have come forward with their subscriptions. Had it not been for that we should have collapsed. I am drawing your attention to this for the reason that I am hoping that the subscriptions will be increased. As you know, the conditions are such that we cannot hope for any amount to be received from the examinations of students, our old source of income. That being so, and as we require between £1200 and £1300 a year for establishment expenses to carry on the work of the College, I hope that in the coming year the subscription will not only be continued but greatly increased. This year we hope they will amount to about £1000. In the near future we must have more, and if we do not have more we cannot carry on the work that we have been doing for so many years.

#### EXAMINATION COMMITTEE.

The following report of the meeting held on Thursday, July 4th, was read and adopted:—

*Correspondence.* A letter (4/6/1918) was received from Mr. Finlay Kerr, suggesting that the written examination in July should be held on the first Monday in the month.

It was resolved: That the Secretary be instructed to reply that the Committee is unable to accede to the suggestion.

**Fellowship Examination.** The Secretary reported that at the Fellowship Examination held on 11th May, three candidates entered, but only one was able to be present, namely, Mr. C. S. Hunting. This candidate was successful. The other two candidates, being on active service, were unable to get leave of absence.

It was resolved: That the examination fees paid these cases be held over until the next examination at which the applicants are able to attend.

**Summer Examination arrangements.** The Secretary reported that the following temporary appointments to the Examining Board had been made by the President:—

Chemistry and Physics—Class A: Dr. J. C. Withers, Ph.D., to act in place of the late Mr. D. S. Jardin.

Biology: Dr. E. J. Schwartz in place of Dr. Bottomley, unable to act on account of illness.

Pathology and Bacteriology—Class C: Dr. W. Bulloch to act as Examiner in London, and Dr. J. Miller to act as Examiner in Edinburgh in place of Dr. McWeeny, who is unable to act elsewhere than in Ireland.

**Educational Certificates.** Educational Certificates Nos. 1706 to 1709 were submitted and approved.

(b) That the following be added to the list of recognised examinations:—

Board of Education "Recognised Examinations" for Secondary Schools:

*As First Examinations—*

1. School Certificate Examination of the Oxford and Cambridge Schools Examination Board.
2. Senior Local Examination, Oxford.
3. Senior Local Examination, Cambridge.
4. Senior Certificate Examination, Bristol University.
5. First School Certificate Exam., Durham University.
6. General School Examination, London University.
7. School Certificate Exam., Northern Joint Board.

*As Second Examinations—*

8. Higher Certificate Examination, Oxford and Cambridge Schools Examination Board.
9. Higher School Certificate Examination, Oxford.
10. Higher School Certificate Examination, Cambridge.
11. Higher School Certificate Exam., Bristol University.
12. Higher Certificate Exam., Durham University.
13. Higher School Certificate Exam., London University.
14. Higher Certificate Exam., Northern Joint Board.

Certificates on Form A, granted on the results of the above examinations are recognised without condition as to subjects. Certificates on Form B are recognised provided the required subjects (English, Mathematics, and two languages) are included.

**Applications from ex-officers and men.** Applications were received for relaxation of the requirements in regard to the Preliminary Educational Examination, from certain ex-service officers and men.

It was resolved to recommend: (a) That each application for a relaxation of the conditions of entry into the profession be considered on its merits. (b) That the certificate of Mr. G. S. Unsworth be approved. (c) That in the cases of Mr. A. D. McEwen, E. W. Allonby, G. Ridley, and G. F. Langford, the Secretary be instructed to reply that the Committee were prepared to accept certificates in general education granted by one of the Examining Boards at any time previous to the date on which the candidate desires to present himself for the first Professional Examination. (d) That the certificate of Mr. W. E. Edge be accepted as qualifying him in respect of general education. (e) That the applications from Messrs. J. Hill, R. O. Rees, R. Winwood, and S. Ghose be not acceded to.

**RESETTLEMENT OF OFFICERS IN CIVIL LIFE.**

The PRESIDENT reported that on April 25 he attended on the Minister of Labour and submitted a scheme for the establishment of a Joint Committee consisting of representatives of the Ministry of Labour, the R.C.V.S.,

and the War Office, to deal with the resettlement of Veterinary Surgeons now on active service in civil life after demobilisation. The scheme was favourably received, subject to the addition of a representative of the Ministry of Pensions on the Joint Committee.

It is understood that the Ministry of Labour will shortly nominate an Appointments Committee to whom the scheme will be submitted.

On April 26 the President, with the Chairman of the Examination Committee, attended a Conference at the War Office, when details of the scheme were discussed. The President afterwards addressed a letter to the Ministry of Labour urging that a representative of the Veterinary Profession should be appointed on the General Committee dealing with the resettlement of Officers after the war.

It was resolved: That the President for the time being be appointed to represent the Veterinary Profession on the General Committee appointed by the Ministry of Labour to deal with the resettlement of Officers after the War.

**VETERINARY STUDENTS AFTER THE WAR.**

The Committee consider that financial assistance will be required by two classes of students:—

1. Registered Veterinary Students whose studies have been interrupted while on active service. Many of these will, without financial assistance, be unable to complete their training.

2. Discharged officers and men who wish to enter the Veterinary Profession, but whose means are insufficient to enable them to undertake the four years course required for qualification.

It was resolved to recommend: That a Sub-committee consisting of General Blenkinsop, Prof. Gaiger, Mr. Garnett, Mr. Mulvey, and Mr. Sumner be appointed to consider the question and to report to the next meeting of the Committee.

**WAR EMERGENCY COMMITTEE.**

The following report of meeting held on Thursday July 4th, was read and adopted:—

**Calling up of Veterinary Students.** The Secretary reported that by Proclamations of April 20 and June 4, all veterinary students between the ages of 18 and 23 who had hitherto been exempted from Military service were now liable to be called up if over Grade III. He had, however, been able to make arrangements with the Ministry of National Service that the calling up notices in respect of students due for the July Examinations should be postponed until after July 13.

**Exemption of Veterinary Surgeons.** The President reported that he had received a letter from the President of the Central Veterinary Society containing a resolution passed by the Society with regard to the formation of an Advisory Committee to deal with the cases of Veterinary Surgeons of military age. This resolution had been forwarded to the Ministry of National Service by the Society, and a negative reply had been received. The President stated that negotiations for the establishment of a Veterinary Tribunal had been in progress for some months past.

It was resolved: That the President be authorised to reply to the President of the Central Veterinary Society and that the President of the College be requested to continue the negotiations now in progress.

**Correspondence.** J. M. Armfield. A letter (8/6/1918) was received from the Committee on work of National Importance asking whether in the opinion of the Committee work as an assistant to a member of the College could be considered as of sufficient national importance, and the Secretary was instructed to reply in the affirmative.

The PRESIDENT: There is one part of these minutes that I want to draw your special attention to, and that

is with regard to the letter from the President of the Central Society. The action of that Society, in my opinion, was very hurried and ill-considered, and the reply that they have received from Sir Auckland Geddes has practically killed the scheme that we had in hand. It was hoped, with every prospect of success, that, had not this action been taken, we should have been able to establish a tribunal for the veterinary profession as a whole, and to that tribunal all cases which are now dealt with by local tribunals and appeal tribunals would have been referred in the same way that such cases are referred in the case of barristers and solicitors, and the dental and medical professions. Departments, however, are like human beings; they have very sensitive consciences, and once a Department has taken up a negative attitude to any question, as has been done in this case, it is extremely difficult, in almost any circumstances, to get them to reverse it in the near future, so that any hope that we had—and we had every prospect of carrying it to a successful issue—has been broken down entirely by this precipitate and ill-considered action of the Central Society. I deplore it extremely, because, in my opinion, it would have been to the benefit of the whole profession had we been able to carry that thing through. I hope that an opportunity may arise whereby we can see a way to again approach the Ministry to reconsider the whole question; but my own opinion is that at the present moment it would be fatal to re-open the question with a view to getting the Department to change their considered opinion.

Sir JOHN M'FADYEAN: Is there any explanation as to why they adopted this step instead of sending the matter to the Council?

The PRESIDENT: There is nothing, except that they have sent a letter to the Ministry, and have received the reply from the Ministry.

Sir S. STOCKMAN: Is there any precedent for any one Society coming along and presuming to represent the whole profession?

The PRESIDENT: No, I do not think so. We cannot deal with them at all; but it is not in the interests of the profession to approach public bodies except through the Governing Body.

Mr. W. J. MULVEY: Has any reply been sent to the President of the Central Council?

The PRESIDENT: No. The report of the Committee directs me to reply.

Sir JOHN M'FADYEAN: I am not at all sure that it would not have met the actual circumstances if the decision of this Council had been that the communication of the Central Society should lie on the table and that the President of the Central Society be referred to the report of this Council meeting for information as to the view which the Council takes with regard to the action of the Central Society. I throw this out as a suggestion.

Mr. GAIGER: Would it not be as well to point out in what way a Central Tribunal would be any advantage over the system of local tribunals. Would it be an advantage to the profession?

The PRESIDENT: I think it is obvious to everybody that it would be an advantage, in dealing with all these regulations, that we as a profession should review all the requirements, both of agriculture and the needs of the army and the different departments employing veterinary surgeons throughout the country, instead of each local tribunal viewing it from the local standpoints. We should view it from the National standpoint. Another object we had in view was that there were certain veterinary surgeons, then not of military age, who had no call upon them whatever, but who patriotically gave up their practice and have served in the forces practically since the beginning of the war to the present time. I have letters from several of these men who want to

come back to their civil practices; having done a good share of service they think that they should be shown some consideration, and we might find a means of relieving them and letting them return to their practices by being able to substitute men of Grade 1 who are fit for overseas duty. In every way that I looked upon it I thought it would be a great benefit to us to have our own Tribunal.

Mr. J. T. SHARE-JONES: I take it from the last item in the report on this matter that the negotiations will be resumed, and that at what will be considered the opportune time a further report will be made to the War Emergency Committee as to the success or otherwise of these negotiations?

The PRESIDENT: That is so. A favourable opportunity will be taken, but at the present moment we are losing time.

#### PARLIAMENTARY COMMITTEE.

The following report of the meeting held on Thursday, July 4, was read and adopted:—

*Fire damage in office and repairs.* The Secretary reported that a fire occurred in the office in the afternoon of Saturday, April 6, and that damage had been done to the walls and to certain furniture, but no important document had been destroyed. The full amount claimed had been paid by the Insurance Societies, and the necessary repairs had been carried out.

*Veterinary Surgeons and Income Tax.* A letter (31/5/18) was received from the Midland Counties Veterinary Medical Association, making enquiries in regard to the effect of the new Finance Bill on the Income Tax payable by veterinary surgeons who would rent accommodation land. The Secretary was instructed to reply that the matter was not one in which the Council could interfere.

*Veterinary Surgeons Bill for South Africa.* A draft of the Veterinary Surgeons Bill for South Africa was received from Col. J. Irvine Smith, with a request for the support of the Council.

It was resolved: That the matter be referred to the Chairman of the Committee, Dr. Bradley, Mr. Garnett, and Sir John M'Fadyean to draft a report and suggested reply to be submitted to the Committee at its next meeting.

*Definition of "Veterinary Surgeon" (Transvaal).* A letter was received from Col. J. Irvine Smith, stating that the definition of Veterinary Surgeon to which objection had been raised had been cancelled.

*Supplementary rations.* The Secretary had reported that he had received the following letter from the Ministry of Food:—

Ref. Li4/23480. Ministry of Food,  
Grosvenor House, W. 1.  
The Secretary, R.C.V.S., 12th April, 1918.  
10 Red Lion Square, W.C. 1.

Sir,—I am directed to acknowledge the receipt of your letter of the 11th inst., and to inform you that Veterinary Surgeons are included in the list of those persons entitled to the Supplementary Ration. They will be graded under Class "D."

I am to add that any further enquiries on this subject should be addressed to your Local Food Office.

I am, your obedient Servant,  
(Signed) J. S. LEAVER,  
Supplementary Ration Section.

*Turpentine Supplies.* The Secretary reported that, having received complaints from members that they were unable to obtain supplies of Turpentine, he had had an interview at the Mineral Oil Production Department of the Ministry of Munitions of War, and had in consequence received the following letter from the Assistant Controller of Supplies:—

29th June, 1918.

Sir,—I am directed to inform you, with reference to your visit yesterday, that this Department considers the supplies of Turpentine to V.S. as a matter of National importance, and every effort shall be made to ensure their requirements being satisfied.

All suppliers to whom licences are issued for Domestic purposes—apart from actual Government requirements or other essential purposes covered by priority certificates—must give preference to medicinal supplies, over any other orders received. Should supplies to your members be refused when stock is available in the hands of the sellers, the circumstance can be reported to this Department, when the licence which has been issued will be subject to revision and arrangements made to issue certificates to suppliers who will see that the needs of the V.S. are properly met.

You are at liberty to make what use you like of this letter, either by circulating a copy of it amongst your members or showing it to any distributors of Turpentine who may decline to consider the claims of your Society.

I am, Sir, your obedient Servant,  
(Signed) F. HOUGHTON FREY,  
Assistant Controller (Supplies).

The PRESIDENT: In proposing that the report be received and adopted, I wish to draw the attention of those members of the profession who may be in need of a supply of turpentine and the steps that they have to take. Over and over again we get matters of importance to the profession put in order, but apparently no notice is taken of what has been done, and the Secretary is inundated with enquiries on the same point over and over again. By noting these things as they crop up at the time the profession can save not only themselves trouble, but a considerable amount of trouble to Mr. Bullock.

Sir JOHN M'FADYEAN: I should have thought that the publication in full of the proceedings of this Council in the professional Journals would be sufficient intimation to all professional gentlemen. A member of the profession who reads no professional journal hardly requires retaining in the profession.

Sir STEWART STOCKMAN: On the other hand, I can assure you that we as a Board are inundated with questions on some of the matters that have been settled by this Council,

#### PUBLICATION, LIBRARY, AND MUSEUM COMMITTEE.

The following report of the meeting held on Friday, July 5th, was read and adopted:—

*Presentations to Library.* The Secretary reported that since the previous quarterly meeting the following presentations had been made to the Library.

Annual Reports: Board of Agriculture, Proceedings under Diseases of Animals Acts; Board of Agriculture for Scotland, 1917; Lister Institute of Preventive Medicine, 1918; National Veterinary Medical Association, 1917; County of Lanark, Veterinary Inspector, 1914-18; Zoological Society, 1917; Ceylon, Government Veterinary Surgeon, 1917; Bengal Veterinary College, and C.V.D., Bengal, 1916-17; Bombay Veterinary College, and C.V.D., Bombay, 1916-17.

Vicious Circles in Disease, J. B. Hurry, M.A., M.D.; The Vicious Circles of Neurasthenia and their Treatment, *ibid*; International Veterinary Congress, Baden Baden, Vol. II of Report (presented by Mr. G. H. Locke); Digestion of Starch by the Young Calf, R. H. Shaw, T. E. Woodward, and R. P. Norton; Efficacy of some Anthelmintics, M. C. Hall and W. D. Foster; Some Common Disinfectants, M. Dorset; Cattle Lice and how to eradicate them, Marion Imes; White Snakefoot or Richweed (*Eupatorium Urticæfolium*) as a Stock-poisoning Plant, C. D. Marsh and A. B. Clawson; Tuberculosis in Carnivorous Animals, W. Reid Blair.

*Journal of the Board of Agriculture and Fisheries; also Leaflets and Orders; Journal of the D.A.T.I.; Journal of Comparative Pathology and Therapeutics; Revue de Pathologie Comparée; Journal of Physiology (per Maj.-Gen. Sir F. Smith); Rhodesia Agricultural Journal; New Zealand Journal of Agriculture; Journal of Department of Agriculture, Victoria, Melbourne; Bulletin of the Central Veterinary Medical Association, Tokyo; The Bloodstock Breeders Review; The Veterinary Review; The Veterinary Journal; The Veterinary Record; The Veterinary News; The British Medical Journal (per Dr. Bradley); The Educational Times.*

Sir S. STOCKMAN: What do we do with these publications?

The PRESIDENT: They are all catalogued and kept.

Sir S. STOCKMAN: The main thing which occurs to me is that a particularly valuable list has been read out, but some of them are not worth keeping over a year. Do we bind them?

The PRESIDENT: No, they are not bound.

Sir S. STOCKMAN: We should have some system of going through them and selecting those we should throw away and those we should keep.

The PRESIDENT: Mr. Bullock does his best when he puts them away and catalogues them. You may refer it to the Library Committee. There was a clean out a few years ago. They are not bound, but they are all put into cases and catalogued.

*Register Advertisements.* A copy for a proposed advertisement in the *Register*, 1919, was submitted, and, with a slight amendment, was approved.

#### SPECIAL COMMITTEE ON VETERINARY STAFF SALARIES.

The following report of the meeting held on Friday, July 5th, was read and adopted:—

*D.A.T.I. Staff Salaries.* Correspondence between the President and the Department of Agriculture and Technical Instruction of Ireland in regard to salaries of the Veterinary Officers was read and the reply of the President was approved.

#### APPOINTMENT OF STANDING COMMITTEES FOR THE YEAR.

*Registration Committee.* It was formally resolved that the Registration Committee should be composed of the whole Council.

*Examination Committee.* Messrs. Bradley, Brittlebank, Coleman, Dunstan, Gaiger, Gofton, McCall, M'Fadyean, McKinna, Mulvey, Share-Jones, Shave, Slocock, Stockman, Sumner.

*Finance Committee.* Messrs. Abson, Blenkinsop, Bradley, Carter, Clarkson, Howard, Lawson, McKinna, Mason, Mulvey, Packman, Sumner, Trigger, Wharam, Wilson.

*Parliamentary and General Purposes Committee.* Messrs. Blenkinsop, Bradley, Brittlebank, Carter, Clarkson, Dunstan, Lawson, McCall, M'Fadyean, McKinna, Mulvey, Slocock, Stockman, Sumner, Trigger.

*Annual Fee Committee.* Messrs. Barrett, Blenkinsop, Bradley, Carter, Gofton, M'Fadyean, Mason, Mulvey, Packman, Sumner, Thomson, Trigger.

*Publication, Library and Museum Committee.* Messrs. Abson, Bradley, Burt, Coleman, Dunstan, Gaiger, McCall, M'Fadyean, Mulvey, Price, Share-Jones, Shave, Slocock, Stockman, Wharam, Wilson.

*Honours and Prizes Committee.* Messrs. Abson, Banham, Bradley, Brittlebank, Gaiger, Gofton, Lawson, M'Fadyean, McKinna, Mulvey, Packman, Share-Jones, Stockman, Sumner, Trigger.

*War Emergency Committee.* Messrs. Abson, Blenkinsop, Bradley, Coleman, M'Fadyean, Mulvey, Price, Share-Jones, Slocock, Stockman.

## AUDITORS.

On the motion of Mr. W. J. Mulvey, it was decided to re-appoint Messrs. Waterhouse and Wilkinson Auditors at an inclusive fee of 16 guineas per annum.

## DATES OF COUNCIL MEETINGS AND EXAMINATIONS.

The following dates for Council and Committee Meetings, and Examinations were fixed:—

*Committee and Council Meetings.*

1918. October 3rd and 4th.

1919. January 9th and 10th; April 9th and 10th; July 3rd and 4th. Annual Meeting, June 4th.

*Examinations.*

1918. Dec. 13th, Written; Dec. 17th, Oral.

1919. July 7th, Written; July 8th, Oral.

Fellowship, May 10th.

## NOTICE OF MOTION.

Mr. W. J. MULVEY gave notice that at the next meeting of Council he would move that Bye-law 62a be altered to read as follows:—

(1) "A student who has obtained a degree in arts, science or medicine, or a degree or diploma in agriculture granted by a University situate within the United Kingdom, or by the Joint Examining Board of the Royal Agricultural Society of England and the Highland and Agricultural Society of Scotland, or by any other body whose degree or diploma in agriculture is approved for the time being by the Council on the recommendation of the Examination Committee, or the diploma of licentiate of one of the Royal Colleges of Surgeons, or of one of the Royal Colleges of Physicians, and who in procuring any such degree or diploma passed an examination in chemistry and also in biology, zoology or botany, shall be exempted from his A or first professional examination and the by-laws and regulations in respect thereof, and shall be entitled in all respects to the rights and privileges which the passing of such examination ordinarily confers, provided always that such student so exempted shall be examined in the whole subject of chemistry in the class B examination."

(2) "A student possessing a degree or diploma of a like import or denomination to one of those enumerated in paragraph (1) hereof, but granted by a university or other examining or licensing authority, other than those mentioned in paragraph (1) shall, if the Council declare its sufficiency for exemption, thereupon become entitled in all respects to such exemptions, rights and privileges as are defined in paragraph (1) of this by law. In any other special circumstances arising in connection with the war, exemption under this by law may also be granted by the Council on the recommendation of the Examination Committee."

Mr. J. T. SHARE-JONES: On the minutes of the last Council meeting it is set forth that Mr. Mulvey gave notice that he would move at this meeting certain amendments to the regulations. I gather from what he has just said that he does not intend now to do that.

Mr. MULVEY: Certain alterations have to be made—

Mr. SHARE-JONES: It is practically moving an amendment to the motion he has already given notice of.

Mr. MULVEY: No, that motion has been withdrawn.

Mr. SHARE-JONES: No, it has not been withdrawn.

The PRESIDENT: The effectual thing is the notice board.

Mr. SHARE-JONES: It is a question of procedure.

Mr. MULVEY: There is no notice on the notice board. It has been taken down and it obviously falls through.

Mr. SHARE-JONES: I desired to move an amendment to the motion of which you had already given notice. I take it that this present motion will be circulated to us before we meet next time in the usual way.

The PRESIDENT: It will be on the agenda for the next meeting.

Mr. MULVEY: It will be suspended on the notice board for three months, that is the official intimation.

Mr. SHARE-JONES: It appears to me to be out of order to give notice of a motion last time and to move another motion this time and that it should not have been printed and circulated with the minutes for this meeting. I had intended to move an amendment and I still wish to move an amendment to the one that has been read to-day.

Mr. BARRETT: May I point out that you may be in a difficulty because there can be no alteration of a motion three months hence. Therefore, I suggest to Mr. Share-Jones that if he requires a modification of the motion he ought to give notice that day of it in order to comply with the by-laws.

Mr. SHARE-JONES: I gather from what has been said that I shall be in order at the next meeting in moving an amendment?

Mr. MULVEY: Yes, I am simply giving notice of what is going to take place at the next meeting.

Mr. SHARE-JONES: At the same time it seems to me that Mr. Barrett is right and that I shall be ruled out in three months time from moving an amendment to Mr. Mulvey's motion.

Mr. BARRETT: I only desire to point out that on several occasions you, Mr. President, have held, and I think rightly, that there can be no amendment proposed, and unless you reverse your previous ruling Mr. Share-Jones will find himself in a difficulty at the next meeting.

Mr. MULVEY: May I point out that there is nothing before this meeting. I have not moved this motion, and so Mr. Share-Jones is not called upon to move an amendment. The motion of which I gave notice last time was taken down from the Board because it was found not to be in order.

Mr. SHARE-JONES: But has Mr. Mulvey had permission to withdraw the motion of which he gave notice last time?

The PRESIDENT: You are quite out of order, Mr. Share-Jones; this motion is not on the agenda for this meeting.

*New Members.* The PRESIDENT: In your name I should like to welcome to this Council two new members—General Blenkinsop and Prof. Gaiger. I am sure we shall benefit from their counsels.

*Vote of thanks.* A cordial vote of thanks was passed to the President, and the meeting terminated.

## ARMY VETERINARY SERVICE

War Office, July 6.

The following Officers have been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the War:—

Maj. (temp. Lt.-Lt. Col.) F. S. H. Baldrey, F.R.C.V.S., R.P.; Temp. Maj. J. W. F. Brittlebank; Temp. Lieut.-Col. H. W. Pitchford; Lieut.-Col. (temp. Col.) G. M. Williams.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, July 4.

## REGULAR FORCES. ARMY VETERINARY CORPS.

Temp. Capt. E. G. Robertson relinquishes his commission on acct. of ill-health (July 5).

To be temp. Lt.:—A. J. Moffett (June 15).

July 5.

Col. (hon. Maj.-Gen.) L. J. Blenkinsop, D.S.O., to be Maj.-Gen. (Apr. 24).

July 8.  
Capt. A. M. Howie, from S. Afr. Vety. Corps., to be  
temp. Capt. (June 22, sen., Nov. 6, 1914).  
To be temp. Lt.:—W. S. Mackintosh (June 18).

July 10.  
Lt.-Col. (Bt. Col.) F. W. Hunt, C.M.G., to be actg. Col.  
whilst holding appt. of D.D.V.S. (May 26).

The following casualty is reported:—

WOUNDED—Capt. N. V. James, atttd. R.F.A.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

Horace Jewell, Capt. A.V.C.				
1914, 1915, 1916, 1917, 1918	£5	5	0	
W. F. Maynard, Romsey	1	1	0	
Frederick C. O'Rorke Major A.V.C.	1	1	0	
John L. Orr, Strabane	1	1	0	
Previously acknowledged	889	10	5	
	£897	18	5	

#### A judgment on the use of Motor Cars.

In Ayr Sheriff Court, Sheriff-Substitute Broun gave his judgment in four cases against four well-known farmers, all in the parish of Kirkoswald, near Maybole, charged with having used petrol or petrol substitute on a journey between their farms and Ayr, for the purpose of driving motor cars, contrary to the Motor Spirit (Consolidation) and Gas Restriction Order, 1918. The defence was that the petrol was used for business purposes to enable them to attend Ayr market. One of the main contentions for the prosecution was that the respondents could motor from their farms to Maybole, the nearest railway station, and thence get the train to Ayr, but the respondents contended that by travelling by motor they saved time in the morning and in the afternoon amounting to about three hours.

In holding the respondents not guilty, the Sheriff-Substitute pointed out that the farmers only travelled once a week, and only maintained that they were entitled to do so once a week. The time saved by the farmers was to be taken into account, and was very

important. People on the land were asked to do all they could to increase food production, yet here were farmers losing valuable time if the prosecution succeeded. By using the motor car the farmer was left unfettered as regarded time. There were unexpected accidents at farms, cattle and horses falling ill and requiring attention, and if the respondents were tied down to taking the train on all these occasions they could not look after them. It was not a very important point that the use of the motor car enabled them to do necessary shopping in Ayr, but possibly a farmer had to be there to get things he wanted to see first of all. If it had been a case of their going daily to Ayr he would possibly have given another decision, but in the whole circumstances it was reasonable that they should go by motor and not by train.—*The Scottish Farmer*.

#### Personal.

Capt. J. W. RIDDOCH, M.B., CH.B., R.A.M.C., who has been awarded the Military Cross, is the only son of Mr. John Riddoch, M.R.C.V.S., 7 Glengyle Terrace, Edinburgh, one of the Edinburgh veterinary officers. Capt. Riddoch was educated at George Watson's College, and is a graduate of Edinburgh University. He has been three years in the East.

#### OBITUARY.

THOMAS SKILTON, M.R.C.V.S., Epsom.

Graduated. Lond: March, 1880.

Mr. Skilton died 5th July, 1918, aged 61.

#### ARGENTINA AND THE EXPORT OF PEDIGREE STOCK.

At the request of the Argentine Rural Society, the Minister for Foreign Affairs of the Argentine Republic has cabled to the Argentine Consul General in London stating that the tattoo marks on all pedigree animals shipped to Argentina must be very clear, otherwise exporters will experience difficulty in securing their entry in the Herd Book.

Breeders, Veterinaries, and others interested in the exportation of pedigree livestock to Argentina should therefore see that the tattooing is as prolix as possible so that difficulty may be avoided on the other side.

Argentine Consulate General,  
London. July 8th, 1918.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1567.

JULY 20, 1918.

VOL. XXXI.

## THE MEMBERSHIP.

The examination returns now published enable us to form a close estimate of the rate of depletion of the qualified practitioners. The number of men who have passed the "Final" this month is shown as 32. In December last it was 31 = 63 for the year. The number of names in the obituary list of current Register is 108 for fifteen months, Jan. 30, 1917 to April 30, 1918; or a rate of 86 for twelve months. It has been considered for some years past that the annual loss has been near about 80, which has usually been balanced by the number of entrants to the profession. The figures given show a difference—deficit of 23. It is certain that a proportion of the 32 men now joining will go to Army service; and that the number going to country practice will be smaller than ever. It is known that there are large districts at present without veterinary practitioners, that many practices have become derelict, and that in other districts men are working to the limit of their powers in the endeavour to keep going the practice of their neighbour in his absence on service. Possibly, as a profession, we are not worse off than others in this time of great endeavour. But the pass lists show that the deficiency in trained veterinarians cannot be made good for, at least, five years hence: and it may well be not for ten.

## ABOUT SEVERAL DISEASES.

The South Africa Report which we reprint in abstract, in common with many similar reports, contains little that is of direct use to men in general practice in Britain; but reading it leisurely over a quiet pipe there are several items which set one thinking. It has been said that Africa has all the plagues of all the ages, and the diseases mentioned in this report, should surely suffice most veterinarians. But the few with which we are too familiar present themselves under new conditions. Tuberculosis—an imported disease, in the herds tested shows percentages of 2.92: 5.88: 5.7: 18.0, and in imports 3.5. Understaffed as they are at present, "very little progress can be made." Can we, with our heavily infected stock and confined areas, hope to show better results?

Again, "anthrax is responsible for more losses than the rest of the contagious diseases combined, except East Coast Fever: is spreading rapidly: a serious menace to human and animal life." And there is the inevitable history of carelessness. There is enough of that in this country, though the recent decrease has been attributed to the reduced importation of bone meal and other infected material. But, considering the enormous vitality of spores, are our people yet sufficiently alive to the danger of its spread?

There is only one case of Swine Fever reported—and a doubtful one at that. What a contrast to the condition of Europe and N. America! One asks, What are the methods in use? Are the pigs grazed, or styed? Has American bacon not yet reached them; for some men hold strongly that rind of bacon or ham may carry the infection—if fed from the waste tub, which plays such a part in the life of styed pigs. Admittedly, pigs are indiscriminate feeders, but it appears that in S. Africa they can be cleanly fed. Why cannot we avoid feeding on material in which we know that decomposition is commencing, or infection may exist.

## THE SYMPTOMATOLOGY OF POISONING FROM SNAKE BITE IN CATTLE.

Aldidge, having observed the death of a young bull from snake bite in Guinea, communicated the chief symptoms he noticed to the Central Society of Veterinary Medicine, which published the case in its bulletin for 1917.

The first thing which was seen, and which caused snake bite to be thought of, was that the animal was down and it was impossible to raise him, and that the head was very extended upon the neck. Fever was present at that time. The bite was quickly found under the hairs of the lumbar region, to the left of the median line. The animal must have been bitten during the night, while sleeping, by a snake which had got into the building where he was.

The following day, the symptoms seen the evening before were more marked. On the third day the appetite had completely disappeared; but the animal showed great thirst. Dyspnea was present, the pulse was small, and the temperature was 100.9° F. On this day a fetid diarrhoea succeeded the constipation which had been observed on the preceding days, and tympany was present. The contraction of the neck was continued, and proved that the action of the poison was exercised principally upon the medulla and the nervous centres. All the locomotory muscles were contracted, especially those of the hind limbs, which were completely rigid. The animal had fallen into almost complete somnolence.

On the fourth day the temperature descended to 99.1° F.; but the general condition remained the same. The animal died on the seventh day, in hypo-thermia.

No local treatment was instituted; because, as anti-venom serum was not available, local treatment was considered useless.—(*Revista de Higiene y Sanidad Pecuarias*).

## Royal College of Veterinary Surgeons.

### EXAMINATIONS IN LONDON.

At a meeting of the Board of Examiners, held in London on July 8th, 1918, for the Written, and on July 9th for the Oral and Practical Examinations, the following gentlemen passed their Final Examination:—

Mr. H. R. Allen	Mr. H. H. Leach
G. Barnett	J. McCunn
R. W. Down	D. E. MacRae
C. W. Heane	K. S. Simpson
T. H. Jones	W. A. Williams

The following passed their Third Examination:

Mr. R. Catmur *	Mr. P. Matthews
T. J. Margaron	J. R. Pratt *

The following passed their Second Examination:

Mr. A. S. Canham	Mr. C. N. Thompson
H. L. Hobson	

The following passed their First Examination:

Mr. A. M. Diesel	Mr. R. C. Holmes
G. Eaton *	H. J. Loveless *
D. A. Gill †	R. G. Nurse
J. Heath	H. Theiler

### EXAMINATIONS IN EDINBURGH.

The following passed their Final Examination:

Mr. R. L. Creery *	Mr. J. Judge
H. F. Downie	J. McAllan
J. K. Irvine	J. R. Rider

The following passed their Third Examination:

Mr. D. Buchanan	Mr. L. L. Jones *
J. Davies *	W. C. Miller *
A. B. Hendry	E. J. H. Sewell
H. V. Hughes	

The following passed his Second Examination:  
Mr. A. K. Cameron

The following passed their First Examination:

Mr. W. L. Downie	Mr. G. B. Taylor
R. S. Smythe	W. Tweed
F. E. Somer *	

### EXAMINATIONS IN GLASGOW.

The following passed his Final Examination;  
Mr. A. L. Robertson

The following passed their Third Examination:  
Mr. W. J. Leyshon \* | Mr. J. Mason \*

The following passed his First Examination:  
Mr. W. McAlleer

### EXAMINATIONS IN LIVERPOOL.

The following passed his Third Examination:  
Mr. C. V. Watkins

The following passed his Second Examination:  
Mr. T. G. Sommerville

The following passed their First Examination:  
Mr. W. J. Parry | Mr. F. H. Manley

### EXAMINATIONS IN DUBLIN.

The following passed their Final Examination:

Mr. J. T. Alcock	Mr. A. J. Kelly
S. Anderson	W. E. Little
C. A. Ewing *	J. A. McCutcheon
W. F. Fennelly	B. S. Parkin
T. FitzPatrick	W. L. Smyth *
T. C. Hall	D. P. White
T. J. Hurley	W. F. White
T. Kelleher	

The following passed their Third Examination:

Mr. P. J. Cooney	Mr. P. C. McGowan
D. J. Donnelly	A. McLean
A. J. Devine	T. F. Moran
P. J. J. Fourie *	C. P. Naser †
M. W. Henning *	V. E. Stack
W. G. Jones †	

The following passed their Second Examination:

Mr. P. V. Byrne	Mr. P. McDonnell
D. B. Colbert	J. P. Nowlan
W. G. Emerson	J. O'Keeffe
G. A. Evans	R. J. Roe
W. R. Henry	J. F. Timoney

The following passed their First Examination:

Mr. P. Carron	Mr. W. E. McDonald
S. W. DeVilliers *	J. E. McIlwaine *
J. A. Flynn *	W. D. Morton *
A. G. Gordon	W. O'Callaghan *
M. A. Heffernan	L. O'Dowd *
E. J. Hughes	M. J. Ryan *
J. Hyde	J. O. Schofelde
C. Lucey	J. Thompson

Marked thus † passed with First Class Honours.

Marked thus \* passed with Second Class Honours.

### NATIONAL VETERINARY MEDICAL ASSOC. OF GREAT BRITAIN AND IRELAND.

#### Preliminary Report.

#### PROFESSIONAL FEES.

At the annual general meeting of the N.V.M.A., held at Red Lion Square, the following resolution was passed:—

"That we send forward to the Branches for comment and criticism certain recommendations respecting night calls, percentage increase on existing fees; fees for insurance examination of horses for soundness, and castration; and payment for the use of the veterinary surgeon's car."

The recommendations are as follow:—

1. That there be a general increase on pre-war fees of "not less than 25 %."
2. That double fees be charged for night work, commencing at 6 p.m. in winter and 8 p.m. in summer.
3. That the minimum fee for examination for soundness should be one guinea; and for castration 10/6.
4. That the scale of fees previously recommended for Insurance Companies be not reduced, but increased 25 %.
5. That Government Offices and Public Bodies shall be requested to pay to Veterinary Surgeons using their own car or trap the same fees as they would have paid to the garage or livery stable for car or trap hire.

It is hoped that Branches of the National will discuss these several matters and forward their comments, etc., for general discussion at the next meeting of the National V.M.A.

GEO. H. WOOLDRIDGE, Acting Hon. Sec.

ANNUAL REPORT, 1916-17, VETERINARY DIVISION,  
DEP. OF AGRIC., UNION OF S. AFRICA. [Abridged.]

In the absence of the Principal Veterinary Officer, in German East Africa on special duty in connection with the outbreak of Rinderpest in that country, I have the honour to submit a report on the work of the Veterinary Division during the year ended 31st March, 1917.

East Coast Fever continues to take up most of the time of the officers of this Division. Taking the Union as a whole, the position has improved, but taking the Provinces individually, I am sorry to have to report that the outlook is not too bright.

Cape Province is in the fortunate position of having no fresh outbreaks during the year. There remain only two areas under quarantine in the Komgha District—and, as no cases of this disease have occurred in this district since May last, I think we can safely look forward to shortly releasing these areas. The existence of the disease in the bordering Transkeian districts still remains a source of anxiety.

Transvaal.—Although the number of outbreaks is eleven less than last year, the position is rather disappointing, as the disease has developed alarmingly in the Pietersburg district, where it was considered it was well under control: there were twelve fresh outbreaks. There were also eight new outbreaks in the Barberton District, but this is a district in which the topographical nature makes the task of combating the disease a difficult one.

There is no doubt that the spread of the disease in the Pietersburg district is entirely due to the lack of co-operation on the part of the farmers. It is evident that two very serious outbreaks had been hidden from the authorities for some considerable time. A further outbreak was discovered at Zoetfontein, whose date of inception is quite obscure, as the owner, although not a thorough believer in dipping, dipped just sufficiently to check mortality. Yet another serious outbreak, whose presence was hidden as long as possible, was discovered at Waterval No. 211. Before these outbreaks were discovered, infection, through the medium of joint dipping and grazing, had spread to other farms, thus the efforts of the officers of this Department were entirely thwarted by lack of co-operation on the part of certain farmers. However, it is hoped that, with measures now taken, the spread of the disease will be checked, and that with the help of the farmers, who have realised the necessity for dealing with this disease with a firm hand and have gone in for dipping tanks (the surest method of combating the disease), there will be an increased improvement in twelve months' time and that the cattle industry will not be seriously interfered with.

It is evident, from various public meetings which the officers of this division have attended, that the farmers are now firmly convinced of the advantages of dipping, and that they no longer look with favour upon concentration and slaughter as a means eradicating the disease.

In the Zoutpansburg district just one death has occurred, but, unfortunately, it keeps a large native area in quarantine. As a precautionary measure a large area has been placed under compulsory dipping.

There have been eight fresh outbreaks in the Barberton District, but, as against this, twenty-four farms have been released from quarantine. Owing to the rugged nature of the country and the consequent difficulties in connection with the erection of tanks, concentration of cattle for the purpose of obtaining dipping facilities has been resorted to, and in a few cases where it was impossible to arrange for dipping, the surviving cattle were slaughtered off and the owners compensated.

The re-infection of the Waterberg District is regrettable, but it is not considered there is much to be feared from this outbreak as, in spite of the fact that there are 487 contacts, only one beast has, to date, succumbed. This very slight mortality is evidently due to the pre-

cautions taken nine months previously in connection with the outbreak on Rietvlei on the Pietersburg side of the border, whereby the block of farms, in the centre of which this outbreak has occurred, was placed under a seven-day compulsory dipping order.

In the Piet Retief District very good progress has been made, and this is entirely attributable to the fact that the district is now well provided with tanks. During the year four farms were released from quarantine. We have, however, had one unfortunate setback on the farm Zendeings Post. The origin of this outbreak has not been discovered, but there is no doubt that had the owner continued dipping his cattle regularly after the first outbreak had been disclosed, he would not only have greatly reduced the mortality from the second outbreak, but he might possibly have avoided a second outbreak. Fortunately there has been no spread of the disease from this new centre of infection.

The seven fresh outbreaks which occurred in the Carolina District were all more or less in the same neighbourhood. Owing to so few of the farms in this district being inhabited by Europeans, the matter of control is a difficult one, but a better supervision of the dipping is now ensured. A tank has been erected by the Government on the farm Steynsburg 91, and the cattle from several infected farms have been concentrated thereon. On one farm, where no dipping facilities were available, the natives were persuaded to slaughter off the whole of the infected herd.

Natal.—It is to be regretted that the progress made towards eradication of the disease in this Province is somewhat disappointing, but it is largely due to the fact that there are so many absentee landowners. 126 outbreaks occurred during the year, as against 91 in the previous year, and the unsatisfactory feature is that many of them had been in existence for some considerable time before they were detected, and were thus a means of spreading the disease far and wide. On the other hand, in a good few instances, the first case of the disease was diagnosed and the prompt adoption of three-day dipping and handdressing had beneficial results.

In a country like Natal, the difficulties of early diagnosis with a disease of the nature of East Coast Fever are considerable, more especially when the farmer fails to do his part in assisting the officers of the Department. As the majority of cases in Natal do not come to light until they have been in existence for some time, and consequently the adult brown tick is prevalent and infected, five-day dipping is now enforced in preference to three-day dipping. Doubtless three-day dipping gives results in the hands of farmers who attend to all necessary details, but as a general practice five-dipping gives better results, as, even if the dip is slightly below strength, there is still a chance of it retaining its tick-destroying properties, whereas the three-day dip slightly below strength is far too weak to ensure the result. In either case handdressing is essential. As a further precaution, in case the quarantine is removed too early through the date of the last death being incorrectly reported, movements of cattle from recently released properties are only permitted provided the cattle can be kept under observation for thirty days on an approved property at their destination, special consideration being given to those cases in which the infection was slight; and for the present ox transport from these farms is only permitted where the to and fro movement can be permitted without outspanning off the owner's property.

The erection of tanks in Natal is proceeding apace, though considerable difficulty is experienced in the case of absentee landowners. It has been found necessary to stop, to a large extent, the holding of central public sales—a very necessary precaution that is generally borne in good part and looked upon as a necessary evil. In one or two isolated cases the slaughter of the surviv-

ing cattle has been resorted to as a means of exterminating the disease.

Considerable progress has been made in the Transkeian Territories during the year and, as a consequence, the cattle are steadily increasing in numbers in the majority of districts. The natives generally are realising the advantages of efficient dipping, and the Transkeian General Council is exerting every effort to provide funds for the erection of as many tanks as possible. The sum of £10,000 is being placed on the Estimates for coming year for this purpose. The allotment of these tanks is being placed in the hands of this Division, and it is our intention to confine our attention to the districts on the border first, in order that we may have a belt of clean areas to act as a buffer for the adjoining districts of the Cape Proper and Natal.

#### Return of Cattle Dipping Tanks.

Province.	31 Mar., 1916	31 Mar., 1917.	Constructing.
Cape ...	1409	1449	5
Transvaal ...	717	867	48
Natal ...	3557	3946	—
Transkei ...	638	673	14
Orange Free State	128	157	16

#### Tuberculosis.

By the lack of funds and the shortage of staff the endeavours of the Department to eradicate this disease are seriously handicapped, and until both these difficulties are overcome very little progress can be made. The question of increasing the amount of compensation payable under the Act has again been brought forward for discussion, but as yet no decision has been arrived at.

In the four closed districts of Cape Province, 4695 cattle were subjected to the test before removal to other districts, of which 137 reacted, and were destroyed, giving a percentage 2.92 reactors.

In the Transvaal there were 18 outbreaks, as against 13 during the previous year, in connection with which 663 cattle were tested, and of which 39 reacted, and were destroyed. The number of outbreaks, however, is by no means a true reflex of the position of the Transvaal as regards the prevalence of the disease, as, with the means at our disposal, it is impossible to follow up the disease properly.

In Natal four outbreaks were dealt with, in the course of which 1339 cattle were tested, and of these 75 proved to be infected, and were destroyed.

Although several farmers in the Mount Currie District were anxious to have their herds tested, with the very small staff operating in the Transkei it was not possible; only one herd was tested, with the result that 47 reactors were discovered in a herd of 360.

No outbreaks were dealt with in the Orange Free State.

Owing to the war, the arrangements made for the application of the tuberculin test over sea, in animals intended for import, have not been made use of; all imported cattle, as heretofore, were tested at the Ports. Of 455 cattle tested, 16 were found to be reactors, and destroyed—a percentage of 3.5.

#### Anthrax.

This disease is responsible for more losses amongst stock than the rest of the contagious diseases combined, with the exception of East Coast Fever, and judging from the number of outbreaks that have occurred within the Union this disease is spreading rapidly, and is becoming a serious menace both to human and animal life, and I am afraid its spread is chiefly due to negligence on the part of the farmers and natives—more especially the latter, who will not bury a carcass intact if it can possibly be avoided. In some

districts in the Transvaal, where anthrax is particularly prevalent, the skinning and opening of the carcass of an animal which has died suddenly of disease is forbidden until such time as a blood smear has been taken and the examination thereof has proved that the animal has not died of anthrax. The advisability of applying this regulation to the whole of the Union is a point which will have to be considered. Various warnings and pamphlets on this disease have been spread broadcast amongst the farmers and natives, in the English and Dutch and Native languages, but I am afraid the results are very disappointing.

#### Glanders.

With the exception of the Cape Province, this disease is not very prevalent in the Union. Glanders is the usual war legacy, and the present war is no exception, and accounts for the increase in the number of outbreaks in the Cape Province (40 as against 22 in 1915-16) where military horses and mules, sold after the German South-West Africa Campaign, were distributed.

An epidemic of influenza affecting equines, a disease which conceals the symptoms of glanders, further abetted the spread of the disease.

*Equine scabies (mange).* With the exception of the Cape and Transvaal, this disease is not very prevalent in the Union (92 and 17 outbreaks, respectively, with 11 in other three provinces). In the Cape Province it is chiefly prevalent in three districts, most of the affected animals being donkeys owned by poor whites and coloured people.

*Epicootic lymphangitis* is only slightly prevalent in the Union, chiefly in the Humansdorp district in the Cape Province. The most expedient, economic, and effective method of dealing with this disease is to destroy the affected animals.

*Contagious abortion* is somewhat prevalent throughout the Union, and its eradication presents some difficulty, as the quarantine policy is, unfortunately, not one that attracts the co-operation and support of the farmers in the detection of the disease. During the year 46 cases have been reported, the agglutination test being applied in most cases.

*Trypanosomiasis.* Nine cases were reported in Natal during the year. The infected animals, 20 in number, were 14 cattle, 5 donkeys, and 1 mule.

*Swine fever.* Only one outbreak was reported—in the Transvaal, and even in this solitary case, owing to the result thereof, there is an element of doubt as to whether the disease was really swine fever.

*Dourine.* On account of the detection of a suspected outbreak of "Dourine" in the district of Herbert, Cape Province, this disease was added to the list of diseases scheduled under the Animal Diseases Act, in order that the Minister might have the necessary legal power to deal with animals suspected of being infected with it. Investigations are still proceeding in connection with the suspected outbreak in Herbert. It is a disease of considerable economic importance. Treatment is unavailing, and the destruction of the infected animals, with payment of compensation, is the only effective method of preventing its spread.

#### NON-PROCLAIMED DISEASES.

Redwater:—Reported spreading in some districts.

Geeldikkop:—Owing to the drought, was not prevalent this year, more especially in the Cape Province. Investigations as to the nature and course are still proceeding.

Quarter Evil:—Was very prevalent in the Transvaal, and caused considerable loss. Inoculation was carried out, and the officers of the Division gave several inoculation demonstrations for the benefit of the farmers and natives with, it is considered, very good results.

**Blue Tongue**:—Less severe, especially in the Cape Province, probably owing to the drought. Inoculation was carried out to a great extent.

**Horsesickness**:—Caused heavy loss in the Transvaal. A large number of equines were inoculated by the V.O., but, unfortunately, losses from a form of "staggers" ensued, and the method had to be stopped.

**Dunzielte**:—In the Transkei, there was considerable mortality amongst equines. Investigations in connection therewith by the Veterinary Research Division are proceeding.

**Mealie poisoning**. In August last, in the Eastcourt Division, Natal, serious illness and many deaths were reported amongst cattle which had been turned into mealie fields. A quantity of "mouldy" mealies were picked up on the fields and sent to the Allerton Laboratory for experiments, with the result that it was definitely proved that "mouldy" mealies are poisonous. No medicinal treatment appears to be of any avail, but the farmer, of course, has the remedy in his own hands—i.e., the removal of all such diseased mealies from the fields before the cattle are turned into them.

#### *Importation of Slaughter Cattle from the adjoining Territories.*

During the year a Port of Entry for stock was established at Liebig's Drift, on the Rhodesian border, and at 31st March, 1917, 1561 cattle had passed through; 11,856 were introduced *via* Mafeking, making a total of 13,417 cattle from Rhodesia. From Swaziland 200 cattle have passed through the quarantine camp on the border. 30,072 were introduced from the Bechuanaland Protectorate. A total of 43,689 into the Union during the year.

#### *Export of Beef.*

The administration of the regulations governing the meat export trade has given the officers of this Division a great deal of extra work, and has taken up a lot of time, especially in Durban, where the whole time of one Veterinary Officer is devoted to it. During the year 53,070 carcasses were examined, and 115,992 quarters were shipped. At Johannesburg, Bloemfontein, and Cape Town, where the slaughtering is carried out at the Municipal Abattoirs, the Municipal V.S. has been authorised to act as Govt. V.O. for purposes of the export regulations. But if, as is anticipated, applications to have their abattoirs sanctioned for slaughtering for export are received from Municipalities who do not employ whole-time Veterinary Surgeons, there is doubt as to whether it would be advisable to sanction such a course. The meat export trade is in its infancy, and every precaution should be taken to ensure it being placed on a sound basis—the quality of meat kept to a high standard, and the regulations strictly adhered to.

#### STAFF.

The Division is still called upon to carry on its duties with a large percentage of Veterinary Officers away on active service. In addition to fifteen Veterinary Officers, twelve Stock Inspectors and East Coast Fever Officers are still with the forces. The Department was also unfortunate to lose the services of Government Veterinary Officer Goulc, who had reached the pensionable age, and retired in February.

With East Coast Fever taking up most of the time of the officers of the Division, their duties are somewhat trying, as it is more often than otherwise their unpleasant duty to impose somewhat irksome restrictions on farmers. The fact that it is their duty to look after the interests of the farming community as a whole, and not merely the interests of the individual farmer, is very rarely understood by the average farmer when he is called upon to suffer on account of the misfortunes, or perhaps negligence of his neighbour. It is, therefore,

greatly to the credit of the officers of the Division that they carry out their duties in such a creditable manner, and I take this opportunity of expressing the gratitude of the Principal V.O. and myself for their continuous devotion to their duties, and for their loyal support. I wish also to record this Division's appreciation of the assistance always so willingly given to its officers by the Magistrates, Native Commissioners, and members of Police Force.

J. D. BORTHWICK, Actg. P.V.O.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

R. L. C. Forrest, Towcester	£1	1	0
James Gregg, Capt. A.V.C.	1	1	0
C. A. Hutton, Capt. A.V.C.	1	1	0
W. A. McDougall, Lt. Col. A.V.C., D.S.O.	1	1	0
Joseph P. Railton, Bulth Wells	1	1	0
A. Richardson, Lieut. A.V.C.	1	1	0
John C. Rowlands, Llanrhadr-y-n-Mochnant	1	1	0
Frank Ware, I.C.V.D. Madras	1	1	0
Previously acknowledged	889	10	5
	£897	18	5

#### ARMY VETERINARY SERVICE

War Office, July 12.

The following are among the Decorations awarded by the Allied Powers at various dates to the British Forces for distinguished services rendered during the course of the campaign. The King has given unrestricted permission in all cases to wear the Decorations and medals in question:—

CONFERRED BY THE KING OF THE BELGIANS.

CROIX DE GUERRE.

Temp. Major J. M. Dawson, M.C., A.V.C.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, July 11.

REGULAR FORCES. ARMY VETERINARY CORPS.

To be temp. Lt.:—W. L. J. Caron (June 1).

July 13.

Capt. T. Bone relinquishes the temp. rank of Major on ceasing to be empld. as Dep. Asst. Dir. of Vety. Servs. (Jan. 25).

Capt. T. Bone to be actg. Major whilst holding a special appt. (Feb. 9).

TERRITORIAL FORCE, ARMY VETERINARY CORPS.

July 17.

Capt. P. J. Simpson to be acting Maj. whilst comdg. a Veterinary Hospital (June 20).

CANADIAN A.V.C.

July 13.

Dep. Asst. Dir. of Vety. Servs.:—Temp. Capt. W. G. Stedman, *vice* Maj. (temp. Lieut.-Col.) C. E. Edgett (May 29).

RECORD PRICES FOR RAMS. At the Merino sheep sale at Sydney, N.S.W., following on the record price of 2500 guineas paid on Monday, 1st inst., for a stud ram, another record Merino ram has fetched 3000 guineas.—*Reuter*.

### The Chemistry of Living Matter.

The cessation of respiration has always been regarded as the best evidence of death. Without some interchange of oxygen and carbonic acid through some of the body tissues life cannot be maintained. In a recent book entitled *A Chemical Sign of Life*, published by the University of Chicago, an account is given of a series of experiments undertaken by Dr. Shiro Tashiro to prove that such interchange is as essential to all forms of living matter, vegetable as well as animal, as it is to man. Directing his attention to the detection of carbon dioxide proceeding from living tissues under varying conditions, he devised an extremely delicate test whereby the presence of one ten-millionth of a gram could be demonstrated with certainty.

The test consisted in the formation of a precipitate of barium carbonate, easily visible through a hand lens, when carbon dioxide is brought into contact with a film of half saturated barium hydroxide solution. The ingenious apparatus in which the test is applied is fully described and figured, and appropriately named a "biometer." Waller and others have long since demonstrated the occurrence of electrical changes in the course of all vital processes, and it has thus been proved that chemical changes also are no less constantly present in all living matter.

"Irritability is the universal sign of life, and by it living matter adjusts itself to its environments"; but whether such irritability is the cause or the consequence of the chemical changes remains to be proved.—*British Medical Journal*.

**THE IRISH DRAUGHT HORSE.** At the annual two-day Summer Show of the Cork Agricultural Association opened on Tuesday, 9th inst., there was a new section for Irish draught horses, in three classes—Stallions, Mares, and Foals of three years and upwards. Three were placed in each of the first two classes, and two in the third. The number of entries is not stated in the report to hand.

### Personal.

At their recent meeting the Senate of Glasgow University awarded the Bellahouston gold medal to Mr. R. T. Leiper, M.D., D.Sc., of the London School of Tropical Medicine, for his contributions to medical helminthology.

[Many of our readers will remember Dr. Leiper's contribution to the Carnarvon meeting of The National V.M.A., and later, a demonstration at a meeting of the Central Society.]

At a recent Investiture held by the King, Lieut. H. D. McKinna was one of the recipients of the Military Cross. He is the third son of Mr. J. McKinna, F.R.C.V.S., of Huddersfield. He was dangerously wounded in the right lung in November last, but is now slowly recovering.

The official record runs:—

Awarded THE MILITARY CROSS.

Temporary 2nd Lieutenant H. D. McKinna, Argyll and Sutherland Highlanders.

For conspicuous gallantry and ability in action. When his line had become very much shaken owing to casualties and shell fire, he displayed great gallantry and skill in reorganising it, and his total disregard of personal danger inspired all ranks at a most critical period.

Capt. H. Leeney intimates that he has received an enquiry (Post Card) from Winchester, but without the writer's signature.

### OBITUARY.

**CLEMENT STEPHENSON, F.R.C.V.S., D.S.C., Newcastle-upon-Tyne.** Graduated. Lond: March, April, 1856.

Dr. Clement Stephenson died in Newcastle on Monday, 15th inst., aged 86: he had been in failing health for some little time. He was one of the first group of Fellows, elected in February, 1877, on the creation of the Fellowship Degree by the Charter of 1876, and served as Vice-president R.C.V.S. in 1888.

His first public work of note was the stamping out of the cattle plague in Newcastle in 1865. In 1877 he was appointed Chief Inspector of Cattle for Northumberland.

In 1880 he retired from practice and turned his attention to stock-breeding, and from that time till recent won championships at all the principal shows for his Black-polled cattle—the Aberdeen-Angus. At the "Royal," in 1887, he took many prizes.

Dr. Stephenson took a great interest in agricultural education, and made a gift of £5000 for the purpose to Armstrong College, which conferred on him the degree of D.C.L. He was unmarried.

### The late Capt. A. R. Routledge.

Capt. Routledge, F.R.C.V.S., one of the best known veterinary surgeons in the wide and important agricultural area of North-east Lincolnshire, was the son of Mr. James Routledge, J.P., of Jarrow, Newcastle-upon-Tyne; he was educated at Kopies Grammar School, Durham, and graduated at the Dick College, Edin., in May, 1895, winning a second FitzWygram prize. He took the Fellowship R.C.V.S. in May, 1903, and in 1906 succeeded Mr. G. H. Kitchin in the extensive practice formerly conducted by Mr. J. Brodie Gresswell, F.R.C.V.S. Mr. Routledge speedily took a prominent position in the County, and held inspectorships under the B. of A. and Lindsey C.C., he acted as Veterinary Surgeon to the Lincolnshire Agricultural Society: was also Examiner to the Worshipful Company of Farriers.

Immediately war broke out he joined the Army (T.F.) and commenced his military duties on August 9th, 1914, at first attached to the Sherwood Rangers. Later, he was in command of the Veterinary Hospital at Bury St. Edmunds, East Anglian Division, and also at Huntingdon. In France he was kicked by a mule, and the injury to his knee necessitated remaining in hospital there for a time. After a period of rest at home, he was sent to York for light duty; and from there to the 3rd Northern General Hospital, Leeds. From here, in April, he was invalided out of the Army, "through ill-health contracted on active service," and then resumed practice in Lincolnshire. The respect of his fellow-townsmen was shown by his election to the Louth Town Council soon after his return to practice.

The funeral took place on Monday, 1st inst., there was a large attendance. Amongst those present at the church and at the graveside were Major Maclean, representing Gen. C. B. Westmacott, A.D.C., Capt. F. J. M. Ingoldby, officially representing headquarters staff, Capt. Somers, representing Army Veterinary Corps, and six captains acted as bearers; the Mayor, members of the Town Council and the principal officials; Dr. A. Gresswell, Mr. F. B. Eve, F.R.C.V.S., and, with the private mourners, Mr. W. Willis, M.R.C.V.S. Striking evidence of the extent of his practice, and the esteem in which he was held for his geniality and skill, was furnished by the attendance of all the leading farmers in North-east Lincolnshire.

The floral tributes were very numerous, including one from the Officers, N.C.O.s. and men of the East Anglian Veterinary Hospital, Huntingdon.

**Cows, Cowhouses, and Milk.** By G. MAYALL, M.R.C.V.S. Second Edition, revised and enlarged. Pp. vii + 136. Price 3/6 net. (Baillière, Tindall, & Cox, 8 Henrietta Street, Covent Garden, London. 1918).

We reviewed this little book when it first appeared; and the second edition does not call for a lengthy notice. Four new chapters have been added, and some revision and re-writing taken place; but the work remains substantially the same. It is a useful popular handbook upon the more essential points regarding cows, their treatment, milk, and milk-production, and will be helpful both to farmers and dairymen who have not yet assimilated the modern teaching in the subjects, and those who are taking them up with little previous knowledge. Its main use to the veterinary surgeon and to the really instructed stockowner is for recommendation to subordinates and others who have still much elementary matter to learn. The author suggests in his preface that after the war "there may be an accession of men to the land desiring to try their hand at cow-keeping," and expressing the hope that the book will be specially useful to them. Doubtless it will; for many such men will find such a volume the best preparation for a more advanced one. Considering its distinctly increased size and the present conditions, its price of 3/6 nett compares very favourably indeed with the 2/6 nett of the first edition.

W. R. C.

#### "SNAIL POULTICE."

The other day I was asked to see a cow which, I was told, had stepped on a piece of glass and had a nasty cut between the claws. I found the cow out in a field, and very lame, with a piece of rag tied round her foot. I proceeded to examine the foot, and when removing the rag the owner (a woman) said, "That's a snail poultice." I have been treating her with it for three weeks, and as she was not getting better I thought it was time for someone to see her."

When the bandage was removed I found, wedged between the claws, two or three snails, which I scraped out with a blunt knife. As I was not asked whether "snail poultice" was any good I did not comment upon the "wonderful treatment;" and, besides, I had been told that "mother had great faith in snail poultice."

Cornwall.

COUNTRY PRACTITIONER.

#### Prevalence of Parasitic Mange.

At Samford Sessions, on Tuesday, 9th inst., John Lait, farmer, Holbrook, was charged with failing to give notice of a horse being affected with parasitic mange.

Mr. Henry Phillips, veterinary surgeon, stated that on June 14th he visited the defendant's premises and discovered a bay cart gelding suffering from parasitic mange. Defendant, when informed of the fact, said he did not know the horse had mange, although he was aware it had skin trouble.

Defendant pleaded not guilty, stating that he had never had a case of the kind before, and was quite unaware that the horse was diseased.

A fine of 30s. was imposed, and defendant was advised by the Magistrates in future to communicate with the authorities at once, or the consequences would be very serious.

William Simson, veterinary surgeon, of Langham, Essex, was charged with a similar offence in respect of the same animal, and pleaded guilty. After Mr. Phillips had given evidence, defendant was fined £3.

Assistant Chief Constable Staunton informed the Bench that the number of outbreaks of parasitic mange notified for the 26 weeks of the present year was 2999, double that of the similar period of last year. It was most important that such cases should be reported.—*East Anglian Daily Times.*

#### The origin of the Percheron.

The following contribution to the history of the Percheron breed is by Leon van Meldert, of Crosby, Harris County, Texas, in the form of a letter to the *Live Stock Journal* :—

"From reading your paper I must conclude that in England you begin to believe that the Percheron horse of France has an Arabian origin. Since this opinion was pointed out to me some years ago I have been investigating the case, and I have found that the facts are quite different.

It was around 1887 that here in America the publisher of the Percheron Stud Books gave out the opinion that Jean le Blanc, an old-time Percheron stallion, was a descendant of Gallipoli. My investigations show that Gallipoli was a Persian stallion, a grey, born in 1803, imported into France in 1813, and who lived till 1821. He may have been an Arabian, but this is only an opinion.

The Percheron horse of France was not existing when Husard père wrote the book, 'Des Haras Domestiques en France,' in 1818. In that book Husard is describing every French breed of horses, and he does not mention the Percheron horse, which became known only when the omnibuses of Paris began to use a grey horse bred in the Perche, Picardy, Flanders, and Poitou, and this horse became one with a real good reputation around 1848. Those who wrote about him from that time were Charles de Soudeval, Ephrim Houel, Charles du Hays, Napoleon de Saint Albin, Eugène Gayot, and Andre Sanson.

Charles de Soudeval says that the Percheron breed has had all its good qualities from a bay stallion coming from the Cotes du Nord. This stallion was Young Rattler, by Old Rattler and a snap mare. He had been imported in 1820 to France, by M. Wollaston, who had a stud farm at the Chateau de Crenan, near Quintin, Cotes du Nord. This horse was born in 1811, and lived till 1836.

This Young Rattler had a great many sons, all dapple greys, who were standing in Normandy and Perche, among them Regretté, Antenor, Malplaque, Meriadec, Pegase, Young Antenor, Eminence, Mortagne, Oxigène, Envié, Francois I., Heliotrope, Oscar, Birmingham, Grlitz, Herbouville, Ulysse, Flibustier, Opicrinus.

According to Ephrim Houel, the importation of Sandy in the Perche made a noted improvement to the breed. This Sandy was a grey stallion coming from England, and he was the sire of two extra good stallions, Conquerant and Sandy.

Another English stallion, Pretender (1829 1842), had a grey son, Omar, who was standing in the Perche. And then another Pretender, born also in England, in 1859, and standing in France from 1865 to 1881, sired the greys Grison, Ardoisé, and Croquelicot, who were also used in the Perche country.

The Norfolk Phenomenon, born in England in 1845, and used in France from 1851 to 1872, had a grey son, Obligeant, who was also used in the Perche district.

The Percheron horse owes, then, most of his qualities to the Hackney breed of England. This is absolutely sure, as the proofs are given here, but nothing shows that there is any relation between the Persian stallion Gallipoli and the actual Percheron horse of France and America.

Charles du Hays did not say that the Percheron horse was descended from the Arabian horse. He wrote 'He has that beautiful grey robe of the Oriental horse.' Nothing more.

Eugène Gayot, who has been the most prolific writer on French horses during the nineteenth century, does not give an Arabian origin to the Percheron horse. His opinion is that the Perche country was the sole factor able to make a percheron horse, even if the colts were imported from the Cotentin, the Vendée, and the Poitou. 'Bretons, Boulonnaises, Bourbourians, Flemish, Cauchois, Picards, etc., are becoming Percherons under the climate and conditions of the Perche' ('Les Chevaux de Trait Fran ais,' pages 224 and 225).

If England wants now to make a cart horse that is able to trot, the foundation stock should be the English Hackney sire crossed on draught mares. By selection and feeding the Hackney horse could be turned faster into a light draught horse than any stock coming from Arabian studs. In Belgium around 1885-1890 the best

light draught horses, named Ardennese, were made by using a Belgian horse on a Hackney mare. The Belgian horse himself is only an overgrown Hackney; he has the same points, the same action, but he weighs 700 lb more. Here in America I have been able to make some kind of a Hackney by crossing Belgian horses on Texas native mares. This is proof that the Hackney must have been used in the creation of the Belgian horse, and if he can make such a heavy horse he must be able to make a lighter one—i.e., a cart horse that is able to trot."

#### Pigs and Tubercular infection.

The Bureau of Animal Industry, U.S.A., has concluded after a series of investigations, that "The exposure of pigs to the faeces of tuberculous cattle is a much more certain cause of their infection than their exposure to milk from tuberculous cows or to pigs infected with tuberculosis."

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1568.

JULY 27, 1918.

VOL. XXXI.

## THE STATE AND THE PROFESSION.

For a considerable portion of its history, the veterinary profession received very little recognition from the State of its economic value to the nation. At a time when Continental States had established efficient and well-equipped veterinary departments and were using them, the only assistance to the profession in this country was the subsidy of the Royal Agricultural Society of England to the London teaching college. From the earliest days the army had required men, and in the days of the cattle plague—in the "sixties" of last century—the Government discovered the existence of the profession; but both before, and for more than a quarter of a century since that time, the civil side of the profession has had little help and but scant encouragement from the State. Five or six years ago there were signs that this period of neglect was passing away, and that the profession was beginning to assume its proper position as an asset to the State; and in the last twelve months there is additional evidence pointing in the same direction.

That this has shown largely in military matters was inevitable; but it has been more noticeable in connection with veterinary work in civil life. Speaking generally, the War Office has treated veterinary surgeons no better and no worse than it is accustomed to treat other professional men whose aid it requires. On the other hand, the actions of other Government Departments have shown some appreciation of the essential part that veterinary surgeons are playing in conserving the national resources, and a readiness to assist their work in various ways.

The two news extracts which we print this week show that Parliamentary use is made of some veterinary work, and the announcement that "the cause and method of spread of Louping-ill" has been worked out at the new Board of Agriculture Laboratory at Addlestone is an asset to the Board. The decision not to call up veterinary surgeons under the Man-Power Act showed recognition of the fact that the few veterinary surgeons still left in the country have become indispensable for the care of our livestock. Along with this, several departmental decisions have greatly facilitated veterinary work. The concessions to veterinary surgeons using motor cars, the special facilities accorded in the purchase of certain controlled medicaments, and the inclusion of veterinary surgeons among the persons entitled to supplementary rations, are all cases in point. Had the same circumstances arisen twenty or thirty years ago, it is certain that our position would have been different.

Much of this is due to the vigilance and ability

with which the chief representatives of the Council have furthered our just claims. Much also probably arises from the present national conditions and prospects, and from the growing appreciation by the Government of the economic value of veterinary work. Our flocks and herds have never been so precious to us as to-day; and the experience of recent years has shown us how greatly veterinary science can aid in preserving them. The continued calling up of our students for general army service lies with the military authorities. How this must certainly affect the supply of veterinary surgeons for years to come is sufficiently evident—as pointed out in this column last week. For years past the number of graduates has not been more than sufficient to meet the requirements, and every man who is worth his salt has found employment readily. But if the action of the recruiting authority continues the number of qualified men will inevitably fall short of the minimum to meet the nation's needs.

## A CASE OF HYDRARGIC ALOPECIA IN A HORSE.

C. Lerena records this case in the *Revue de la Société de Médecine Vétérinaire de Buenos Aires* for 1917. A black horse, in good condition and with no history of disease, presented a hyperplasia of the left hock, probably due to a traumatism. Lerena applied a friction of biniodide of mercury ointment, which was repeated seven days later. At the end of some time the horse lost his coat, remaining completely depilated. No symptoms of hydrargism were presented; and an examination of the urine for mercury gave a negative result. The latter fact is explained by the small quantity of mercury which could have been absorbed, and by the time which had elapsed since its application.

It is difficult to understand how the mercury could have caused the depilation, in view of the minute quantity of it absorbed by so small a surface. Lerena thinks that perhaps an anaphylactic "shock" was produced in the patient after the second application of the mercury.

Lerena believes that the diagnosis of hydrargic alopecia was confirmed by the fact that the horse grew a coat of hair without any treatment, and also because it was possible, by the examination of the skin and by the circumstance that the animal had been co-habiting with others, to absolutely exclude the possibility that the case might be one of ringworm.

Lerena also states that, when a student, he treated a young chestnut horse affected with

arthritis with repeated frictions of strong mercurial ointment on the carpal and tarsal joints, and in this case also falling off of the hair took place. From these facts, he deduces the following conclusions:—There are subjects in which, from an idiosyncrasy, a single mercurial friction suffices to produce Hydrargic alopecia.

A veterinary surgeon, in a case of equine alopecia, should regard as an important point in diagnosis an enquiry as to whether the horse has previously undergone a mercurial treatment.

#### THE INTRAPALPEBRAL MALLEIN TEST.

Lanfranchi published an article upon this subject in *Il Moderno Zootro* for 1917. The very large number of horses upon which he has practised this test has enabled him to observe facts which in certain directions rectify some ideas which he has expressed in former works.

In 1915, Lanfranchi considered that a previous intrapalpebral mallein test did not influence successive tests in either eyelid in the sense of modifying the reactional phenomena of general character; and he believed that the local phenomena were even made more evident. This is true in general; but Lanfranchi has observed that, in some animals, repeated tests in the same eyelid produce a more or less accentuated sclerosis of the intrapalpebral connective tissue. This, in addition to the greater resistance which the eyelid offers to the penetration of the needle, hinders the mallein from penetrating wholly into the thickness of the tissues. The result is to modify the local reactions, the appearance of which is delayed for periods varying in accordance with the extent of the sclerosis of the eyelid. Moreover, the edema which is produced is not sufficient in volume to permit a decision that the result is positive.

These drawbacks are avoided by injecting the mallein into the upper eyelid whenever the lower one presents sclerosed connective tissue. The technique is the same; and the reactional phenomena are equally intense.

Lanfranchi also refers to the question of the adaptation of the organism to mallein. At first he believed that the tissues involved by previous injections did not lose their special affinity for mallein; and he has recorded the fact that Galtier, in one month, was able to repeat the classic reaction eleven times in a glandered horse. This view also is true in general; but in practice Lanfranchi has observed that there are animals which have been subjected to previous injections which do not react if the injection is repeated before a certain time has elapsed. Hence it is necessary to establish a term within which it is possible to repeat the test without risk of diagnostic errors. Studies made with this object have led Lanfranchi to deduce that in certain animals the term may be fixed at seven or eight days, while in others it is necessary that eleven or twelve days should elapse. In view of this diversity, he thinks that when a negative intrapalpebral reaction is obtained in animals which have previously been submitted to the test, and the exact time of the previous test cannot be ascer-

tained, at least fifteen days should be allowed to pass before submitting them to a new injection. Without these precautions it is possible that horses may be considered healthy when in fact they are glandered.—(*Revista de Veterinaria de Espana*).

#### A METHOD OF RUPTURING OVARIAN CYSTS.

Prof. W. L. Williams, in the course of the clinical demonstration upon sterile cows which followed his paper on Contagious Abortion before the American V.M.A. last August (*vide V.R.*, Dec. 29, 1917, page 260), demonstrated a modification in the method of rupturing ovarian cysts. He regards the common method of rupturing such cysts through the rectum as being, on the whole, very unsafe. A few cysts which are very thin-walled can be ruptured per rectum; but with the majority the procedure is dangerous. Williams prefers the following method, which requires the aid of a co-worker. He introduces his hand into the rectum, grasps the ovary, draws it backwards over the vagina, and holds it there. The co-worker then inserts his hand into the vagina, grasps the ovary as it lies in Williams' hand, and ruptures the cyst from the vagina. Considerable force may be necessary to effect the rupture; and therefore Williams prefers this method to the practice of exercising pressure from the rectum.—(*Journal of the American V.M.A.*)

#### VICTORIA VETERINARY BENEVOLENT FUND

A Quarterly Meeting of the Council was held on Friday, July 5th, at 10 Red Lion Square, London, W.C., when the following members were present:—Mr. S. H. Slocock, President, in the Chair; Messrs. E. Whitley Baker, G. A. Banham, W. F. Barrett, J. Dunstan, F. W. Garnett, P. J. Howard, J. McI. McCall, J. W. McIntosh, W. J. Mulvey; Sir S. Stockman; Messrs. H. Sumner, W. J. Young; P. J. L. Kelland and F. Bullock, Hon. Secretaries.

Apologies for absence were received from Messrs. H. J. Dawes, F. L. Gooch, J. Ewing Johnston and T. S. Price.

*Constitution of Council.* The Hon. Secretaries reported the constitution of the Council under the new bye-laws as follows:—

Representing the National Veterinary Association:—

Dr. Bradley, Prof. Wooldridge.	
Central V.M.A.	J. W. McIntosh.
Midland Counties V.M.A.	H. J. Dawes.
Royal Counties V.M.A.	J. Willett.
Southern Counties V.M.A.	The Secretary. *
S. Durham & N. Yorks V.M.A.	"
Western Counties V.M.A.	"
Lincolnshire V.M.A.	"
V.M.A. of Ireland	"
N. Ireland V.M.A.	J. Ewing Johnston
D.A.T.I. V.O. Association	The Secretary. *
Connaught V.M.A.	"

National Vety. Benevolent and Mutual Defence Society,

H. Sumner and S. H. Slocock.

Royal College of Veterinary Surgeons,

Sir J. McFadyean and W. J. Mulvey.

Representing the Members of the Society:—

G. A. Banham, F. L. Gooch, J. McI. McCall,  
A. Spicer, W. Jackson Young.

\* Notices of Meetings are sent to the Secretary in cases where the Association has not yet nominated a representative.

*Ex-officio—**President—S. H. Slocock.**Vice-Presidents—J. Dunstan, T. S. Price,  
R. C. Trigger, E. A. West.**Trustees—Sir S. Stockman, F. W. Garnett,  
W. F. Barrett.**Hon. Secs.—P. J. L. Kelland, F. Bullock.*

The minutes of the previous meeting having been published were taken as read, and confirmed.

*Report of Hon. Secretaries, 4th April, 1918.*

Since the previous quarterly meeting our efforts have been mainly directed to the collection of subscriptions in arrears. There still remain, however, a number of outstanding subscriptions, and the number of new subscribers secured is very small.

On the other hand, Donations have been received amounting in all to over £90, inclusive of the grants received from the Boltons Cinema. One of these Donations is for £50 from a young graduate who desires to remain anonymous, an exceedingly generous and welcome gift. Another sum of £10 came from a donor who is not a member of the profession, and who gives special directions as to the disposal of £5 of the amount, the gift again being anonymous. A further anonymous donation of £5 6s. was received from a member; and the Midland Counties V.M.A. has voted £10 10s. Several members of this Association have also taken collecting boxes. We should be grateful if the Secretaries of other Societies would take boxes themselves and ask their members to do the same. Many veterinary surgeons are suggesting to clients, in cases where otherwise no charge would be made, to pay to the collecting box.

We have also been gratified to learn from Mr. J. Hammond, of Bale, that his late father left a legacy of £100 to the Fund. The amount will be forwarded when the will has been proved.

The following is a list of new subscribers and donations received:—

*New Subscribers—*

P. J. Turner, Capt. A.V.C.	1	0	0
W. Stothert, Major A.V.C.	2	2	0
W. J. Young (also Life Member)	1	1	0
M. St. G. Glasse, Lt.-Col. A.V.C.	1	2	0

*Increased subscriptions—*

W. A. Hancock	1	1	0
T. Salusbury Price	3	3	0
E. W. Baker	1	1	0

*Donations—*

Bolton's Cinema	10	10	0
Shipley's Collecting Box		7	0
Midland Counties V.M.A.	10	10	0
W. W. Smart	1	1	0
Anonymous	10	0	0
Woodger & Broad	2	0	0
Mrs. Stuart		10	6
W. W. Anonymous	5	5	0
"Michael"	50	0	0

The donations will, of course have to be invested in accordance with bye-laws.

With regard to investments, there was received in donations last year the sum of £135 13s. 6d. Of this we invested £100 in War Bonds, leaving £35 13s. 6d. to be dealt with. Since 1st January the sum of £145 0s. 3d. has been received in donations, making a total to date available for investment of £180 13s. 9d. The sum of £100 13s. 11d. has been invested in the purchase of £183 7s. 4d. Consols, bringing our holding in Consols up to the round figure of £4000. There still remains, therefore, the sum of £80 which must be invested in accordance with bye-laws.

Our available balance for current relief is £70, which is only sufficient to carry us to the end of August. The

outstanding subscriptions, even if they were all received, will not be nearly sufficient to meet our present calls to the end of the year, and many of the cases on our books are really deserving an increase on the 10/- maximum we now pay.

As the Council by its reconstitution is now fairly representative of the profession, we suggest that the members should be willing to act as local representatives of the Fund. Printing and paper cost so much in these days that it is really an extravagance to charge the Fund with the cost of a general appeal by circular, when probably better results could be obtained by friendly propaganda. As one of our members well says, "It would do some of our non-subscribing members of the profession good if they could only see what 10/- a week means to some of the unfortunate one."

It was resolved:—That the report be approved, and that the heartiest thanks of the Council be conveyed to the donors. That a special vote of thanks be accorded to "Michael" for his very munificent gift.

*Cases.* It was resolved to continue the grant in cases Nos. 10 and 11 at the rate of 10/- per week.

Mr. Kelland reported the result of enquiries he had made in cases Nos. 22 and 24, and it was resolved:—(Case 22) That in view of the fact that the recipient is over 80 years of age and that one of her daughters is an invalid, the grant be increased to 15/- per week. (Case 24) That in view of the recipient's ill-health, the grant be increased to 12/6 per week, and that the case be recommended to the favourable consideration of the National Veterinary Benevolent and Mutual Defence Society.

The Hon. Secretaries reported that recipient No. 37, a member of the College, suffering from an insurable disease, to whom a grant of 10/- per week had been paid, had died in Middlesex Hospital, in April.

*Dates of Meetings.* It was resolved that the Quarterly Meetings of Council be held on the same dates as the Quarterly Meetings of Committees of the Royal College of Veterinary Surgeons.

## MEMBERSHIP EXAMINATION, R.C.V.S.

## CORRECTION.

The two names, Mr. H. V. Hughes and Mr. L. L. Jones, who passed the Third examination (p. 18, last week's issue) should appear under Liverpool instead of Edinburgh: and that of Mr. C. V. Watkins under Edinburgh in place of Liverpool.

It may be noted that as a matter of fact the students from Glasgow and Liverpool were examined at other centres—either London or Edinburgh.

## ABBRIDGED REPORT OF THE CHIEF VETERINARY SURGEON, SOUTHERN RHODESIA, 1917.

*African Coast Fever.* A fresh outbreak occurred on the farm Engwa, in the southern part of the Umtali district. The degree of infection was most intense—out of 149 head involved only 37 remain. There is no doubt that this outbreak was the result of a movement of cattle, under somewhat peculiar circumstances, from the southern part of Melssetter district two years previously, and that the existence of infection during this period was masked by the use of a dipping tank. Fortunately the infected area was in a very isolated position, and no extension of infection took place.

After over 11 years' freedom from disease, an outbreak occurred on the farm Lounton, Victoria District, situated in an isolated position, away from any main road or path, and over 100 miles from the nearest centre of infection. Shortly afterwards infection was discov-

ered amongst cattle on three immediately adjoining farms, and, after a lapse of several months, on two farms within a few miles and on the Victoria Common-age, about 25 miles distant.

[There are reports of minor outbreaks in other four districts. Those given here show some of the problems concerned in preventive measures.]

The number of fresh outbreaks during the year was 13, with a mortality of 43 head, as compared with 20 and 382 respectively for the previous year.

Short interval dipping is one of the most effective methods at our disposal of dealing with Coast fever. "No ticks, no Coast fever," is axiomatic, but under local conditions the former state is impossible of achievement. The complete eradication of infection is possible, however. It has been eradicated from many districts in Rhodesia and the Union, and it can be eradicated from those in which it at present exists. I have no hesitation in saying that if every area carrying infected ticks could be accurately defined the disease would be eradicated within a period of two years by our present methods. It may well be asked why these areas cannot be so defined and dealt with. The reply is, to my mind, very simple. In the majority of cases the disease has been in existence for several months (two years in the Engwa case) before it is brought to our notice. Meantime infection has been disseminated, which may and frequently does not manifest itself for another extended period, and so the cycle goes on, with the result that we are generally at the heels of the disease instead of in front of it. In dealing with the outbreaks, the known infected areas are a comparatively simple proposition; the unknown and unsuspected we cannot combat. To remedy this state of affairs universal compulsory effective dipping of cattle throughout the Territory has been proposed. Whilst the value of the proper use of the dipping tanks is fully recognised, it may be stated as a fact, and not as a matter of opinion, that weekly dipping, however effectively practised, will neither eradicate Coast fever nor prevent its spread. It is true that as ticks are reduced in numbers by dipping the chance of the disease being propagated and disseminated is correspondingly lessened; at the same time dipping may mask infection for an indefinite period and result in recrudescences on areas where it had been regarded as a thing of the past and in fresh outbreaks on previously clean areas. This point of view is clearly and concisely expressed in the Supplementary Report of the African Coast Fever Committee as follows:—"Such dipping may prevent any noticeable number of deaths when Coast fever exists, yet cattle moved from such areas may, and have been the cause of carrying the infection with them."

These remarks are not to be taken as reflecting any doubt in the writer's mind as to the value of dipping as a general prophylactic measure; they are simply intended to forestall the disappointment which is bound to result if a scheme of universal compulsory dipping at seven day intervals is relied upon for the eradication of Coast fever.

**Quarter-evil.** The mortality from this disease, which began in November, 1916, persisted throughout the year in Matabeleland, a total of 133 deaths being reported.

**Anthrax.** Three outbreaks occurred on farms in the Mazoe and Salisbury districts. The diseased carcasses were cremated and the in-contact animals, 615 head, vaccinated. The total mortality was nine head.

**Tuberculosis.** Although no case of the disease came under the observation of the Department, several head of Rhodesian cattle showed tuberculosis lesions on post-mortem inspection at the Johannesburg abattoirs.

**Contagious Abortion.** The existence of infection was diagnosed in four herds. Unfortunately there is no satisfactory method of treatment capable of adaptation

to local circumstances, but, as far as possible, infected animals are isolated, the aborted fetuses destroyed and the farm or area involved placed in quarantine for an extended period.

**Fluke Disease of Cattle.** This affection appears to be increasing. During the drought a heavy mortality occurred in various districts. A few animals were treated with *Extractum liquidum filicis*, B.P., with most promising results.

**Horse Sickness.** The total mortality reported was 107 head, mostly horses. As most of the mules in the country and a considerable number of horses have been immunised, and as many horses possess a certain degree of resistance from several years' exposure to infection, this mortality indicates a very heavy infection during the season.

**Rinderpest.** Early in the year reports were received from Veterinary Officer Hooper-Sharpe, attached to General Northey's Column in East Africa, that as a result of the many movements of cattle caused by the military operations rinderpest infection was spreading towards the border of Northern Rhodesia. Full reports of the excellent work done by this officer, under the most trying and difficult conditions, have already been submitted. The magnitude of the work of dealing with rinderpest in such a large area and the menace to the whole of South Africa by the southward spread of infection were realised by all the Administrations concerned, and Mr. C. E. Gray, Principal Veterinary Officer of the Union, was appointed Commissioner in charge of operations, and proceeded to East Africa with a staff of veterinary surgeons and complete equipment. The latest reports show that satisfactory progress has been made in combating the disease and that there has been no further extension southward.

J. M. SINCLAIR, Chief Vety. Surgeon.

The foregoing outline of the work in Southern Rhodesia for 1917 offers little of direct interest to the home practitioner. Rinderpest is a forgotten threat in this country and the note on the fight that the South African Veterinary Service are making against it in East Africa will not come home to the understanding of many practitioners here.

African Coast Fever is probably more familiar—at any rate by name—to the younger members, and it bulks largely among the many problems to be faced in Africa. This is exemplified by the reports to hand of "Committee of Enquiry on African Coast Fever, Quarter Evil and Epizootic Diseases of Cattle." Why this enquiry was instituted is not definitely stated, but there is evidence of differences and of dissatisfaction in, at least, a section of the farmers, in the remit to the Committee, which runs:—

(1) To enquire into and report on the origin of and circumstances attending recent outbreaks of African Coast Fever.

(2) enquire into and report on the adequacy of the measures taken hitherto to prevent and suppress African Coast Fever, and to suggest other measures.

(3) enquire into and report on the circumstances attending the recent outbreaks of quarter-evil; and

(4) consider measures for the control and prevention of epizootic diseases of cattle:

Five gentlemen were appointed for the purpose, with a "request that you, or any two or more of you, do, as soon as the same can conveniently be done, using all diligence, report to me your proceedings in writing." And the necessary "power to enquire of and concerning the premises by all other lawful ways and means whatsoever." It is dated, Salisbury, 10th Aug., 1917.

It may be noted that no veterinarian is included—very possibly because the right men could not be spared

in this time of pressure. Their first meeting was held on 13 Aug. and their Report is dated 26 October, 1917, signed by four of the members, and a Supplementary report, by the fifth member, dated 1st Dec.

Obviously, charges (1) and (2) of the remit indicate the chief points of the trouble.

The principal report is a fairly full one, and covers 19 pages of foolscap. It includes many subsidiary questions not distinctly specified, but which are necessary for a full consideration of the question. The following extract is one of several similar, and gives some idea of the position. The whole report is of interest as a chapter in the history of the fight against a disease of cattle.

"The outbreak at Melsetter was reported to the Veterinary Department in August, 1914. It occurred on the farm Nooitgedacht, where no disease is known to have existed since 1904, and at a very considerable distance from the seat of a previous outbreak in 1912. The local Cattle Inspector diagnosed the disease as African Coast Fever, and took prompt action by instituting temperature camps and removing healthy animals to clean veld. On the arrival of the necessary outfit, spraying was resorted to in the absence of a dipping tank. As soon as the Cattle Inspector's diagnosis was confirmed by an examination of blood smears, a veterinary surgeon was despatched to take charge. The methods adopted resulted in a total cessation of mortality in a short time. The survivors of the herd were retained for some five months on clean veld. Thereafter they were allowed to return to infected ground, and disease again broke out among them. The owner of the cattle holds the Veterinary Department responsible for this movement. This is strenuously disputed by the latter. If it is desired to decide between this direct conflict of evidence by the assistance of surrounding circumstances, it might be said, on the one hand, that the owner would not court disaster by removing his property to a dangerous area, and on the other hand, that the veterinary officers who had taken pains to eliminate disease from the herd were not likely to subject it to inevitable re-infection. There is evidence that the owner maintained that the disease was gall-sickness, and threatened to shoot the officer in charge if he destroyed any of the cattle; it is not, therefore, improbable that a person holding these views would see no risk in removing the animals on to infected veld.

The outbreak at Nooitgedacht was followed by others, often at places widely separated, until 39 farms were infected by the middle of 1916. Many theories have been advanced as to the cause of this dissemination of disease. The veterinary surgeon now in charge bluntly attributes it to cattle straying, or illicitly moved, from infected veld. A large section of the local residents warmly resents this view, and ascribes the spread of the disease to the laxity of the veterinary staff and the carrying about of infected ticks on grass, hides, dogs, etc. Some regard the veterinary officers and police, with their retinues, as most likely to have carried ticks, and thereby the disease, from the infected areas in which they had been carrying out their duties. The veterinary surgeon, in response to the question why, if illicit movements took place, prosecutions did not follow, stated that although there was a moral certainty of such movements, it was impossible to secure legal proof, and instanced a case of a person giving him information of an illicit movement which he was unwilling to give in a court of law."

But the professional question to which the chief interest attaches is Compulsory short interval dipping for the whole country. The Supplementary report is mainly devoted to arguments in favour of this procedure: indeed one might imagine that this reporter went to the Committee as the advocate of the Agricultural Union,

with a creed that universal compulsory dipping is the one way necessary to rid the country of the disease.

Against this it is contended that—whilst it is fully recognised that effective compulsory dipping is an absolute necessity in controlling the disease—dipping at seven days interval, which has since been provided for by an Ordinance, will not, and cannot, *per se* clear the country of the disease. The conclusion of Mr. Watkins-Pitchford, in his work on "Dipping and Tick-destroying agents," is clear on this. He says:—

"Our knowledge of the disease East (African) Coast Fever and of the life history of the brown tick—the chief transmitter of the disease—shows clearly that if we are to make sure of destroying the tick—and with it its infectious germ—we must attack it during the brief space that it spends engorging itself upon the blood of its host, the ox, and if we fail to ensure its destruction during this brief interval it will, by its survival, involve us in the risk of the perpetuation and extension of the disease. If, therefore, we are to make sure that no tick is to survive, which once gains access to its host, our destructive attacks must be so timed as to leave no interval during which a tick may engorge itself and—potent for further mischief—leave the body of its host.

When we learn that a brown tick may complete one of its periods of attachment to its host in so short a period as three days—or even less—we shall see that our attacks (if we are to cut off all possibilities of escape) must be at correspondingly short intervals."

It is this "three-day feed" in the life cycle of the *Rhipicephalus* which makes the seven-day dipping interval sufficient to reduce the amount of infection, and, as they say, to "mask the disease." And so long as this condition persists the disease will be existent in the country, since larvae and nymphæ may become infected in three days, and are able to transmit the disease during the following stage of their cycle. Numerous instances have occurred in the field of outbreaks in herds which have been regularly dipped at seven-day intervals. Such outbreaks are usually easily dealt with, and as a rule with a very low mortality.

Three-day dipping as a general preventive measure is, of course, not a workable proposition.

The following sentences are findings of the Committee on the question of suppression and prevention—No. 2 of the remit:—

"The preponderance of evidence taken by the Committee does not show that the system of dealing with outbreaks could be improved upon."

"The Veterinary Department claims that although it has not eradicated African Coast Fever, it has succeeded in keeping it in control, and points to the cleaning up of Matabeleland, and the comparatively small number of deaths from the disease. The return furnished showing the number and distribution of outbreaks and the resulting mortality, bears out this claim."

"As we are satisfied as to the efficiency of the methods resorted to for stamping out disease in the specific localities where it is detected, we have nothing to suggest in that direction. As to the prevention of the disease, it has been already indicated that we consider that this can best be done by the destruction of the tick, and we believe that such destruction can for all practical purposes be gradually accomplished by the adoption of universal dipping."

And in a further report by two of the Committee who were deputed to confer with the authorities of the Union S.A. in continuance of their enquiry, it is stated:—

"We have carefully studied the methods adopted in the Union in dealing with actual outbreaks of disease and preventing its spread. It does not appear necessary to detail them here, as they are no better calculated to

accomplish their object than those at present in operation in Rhodesia. Under the Union law, cattle illicitly moved are subject to destruction; it is said that the application of this law has had a most marked effect in preventing illegal movements. It is doubtful whether the evil of such movements in Rhodesia requires such drastic action."

There we must leave this interesting report for the present.

#### PARLIAMENTARY.

In the House of Commons, July 18th, 1918.

##### LIVE STOCK.

Mr. PROTHERO: . . . As to live stock, veterinary science has now got a magnificent laboratory equipped in Surrey, and I hope it will lead to a great advance. The health of the live stock has been on the whole extremely good. There has been parasitic mange among horses, but there is a great reduction in sheep scab, and up to a few days ago I could have said a great reduction in swine fever, and that in spite of the fact that the Board early last year relaxed its regulations in order to encourage the upkeep of pigs. The numbers of the live stock in England and Wales may be of interest to the Committee. I will compare the returns of June 4, 1916, and June 4, 1917, with the estimate for June 4, 1918. In the number of dairy cattle there was an increase in the present year on the figures of both the preceding years. The number of beef cattle over one year old shows a slight diminution on the figures of 1917, but an increase on those of 1916, and that of all cattle under one year shows an increase over both periods. The total net result is a diminution of 27,000 head of cattle on the figures of 1917 and an increase of 330,000 on the pre-war period of 1914. The number of sheep shows a decline. This was mainly due to the disastrous lambing season of 1917. It has already been partly counteracted by the more favourable season of 1918.

The pig population of the country declined last year very seriously from October onwards, but the decline has now been arrested. Individual land-owners have taken up the question of increasing the number of pigs with great vigour. In Gloucestershire, for instance, the hon. member for the Wilton division has been instrumental in establishing 65 pig clubs. The Rural League has set up 130 in different parts of the country, and many agencies are working in the same direction. Were I quite sure of the supply of foodstuffs and its distribution, I should regard the situation as promising.

July 22, 1918.

##### THE LABORATORY OF THE BOARD OF AGRICULTURE.

Sir R. WINFREY, Parliamentary Secretary to the Board of Agriculture (Norfolk, S.W.), replying to Mr. Runciman regarding research work in animals' diseases and the immunization of animals from native and tropical diseases, said:—I am glad to say that the Board's laboratory at Addlestone, near Weybridge, is now practically completed, and that already several scientific investigations have been undertaken there. The chief of these are in regard to louping-ill and the poisoning of cattle by ragwort and by bracken. Useful results have been obtained in all of them, especially in regard to louping-ill, a disease which has for many years placed a heavy burden on sheep farmers in various parts of the United Kingdom. Its cause and the method of its spread have been discovered, and it seems quite possible that the remedial measures necessary will be such as can be carried out without the need for restrictions on the movement of sheep.

As regards preventive medicines, the laboratory pre-

pares and sends out anti-swine fever serum at the rate of about 6000 doses per month, and anti-abortion vaccine at the rate of about 1700 doses per month. The best methods for immunizing British live stock against tropical diseases before export are also continuously under consideration, and I understand that good progress has been made in this study.

The laboratory staff has been depleted by recruiting for the veterinary services of the Army, and it is feared that some of the work may have to be suspended if any further men are taken for military service. I am of opinion that the laboratory, which, as the House may remember, owes its existence mainly to the efforts of my right hon. friend, is doing excellent work, and, as regards the future, will play a considerable part in agricultural re-construction.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

William Anderson, Keith	£1 1 0
F. G. Ashley, Dalston	1 1 0
Francis A. Ball, Ormskirk	1 1 0
Geo. L. Bradley, Lieut. A.V.C.	1 1 0
John Arthur Brew, Capt. A.V.C.	1 1 0
John Cameron, jun., Capt. A.V.C.	1 1 0
Dr. W. H. Dalrymple, Louisiana, U.S.A.	1 1 0
John Bowden Garside, Lieut. A.V.C.	1 1 0
David Hamilton, Ballina	1 1 0
E. P. Hearne, Major A.V.C.	1 1 0
Charles Holland, Capt. A.V.C.	1 1 0
H. L. Jones, Beira, P.E.A.	1 1 0
T. J. Lewis, Lieut. A.V.C.	1 1 0
E. S. W. Peatt, Capt. A.V.C.	1 1 0
William Penhale, Holworthy	1 1 0
Charles W. Perrin, Capt. A.V.C.	1 1 0
John F. Rankin, Major A.V.C.	1 1 0
Stewart R. Rippon, Capt. A.V.C.	1 1 0
W. L. Sheffield, Capt. A.V.C.	1 1 0
J. M. Smith, Capt. A.V.C.	1 1 0
Guy Sutton, Major A.V.C.	1 1 0
Previously acknowledged	897 18 5
	£920 19 5

#### ARMY VETERINARY SERVICE

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, July 19.

##### REGULAR FORCES. ARMY VETERINARY CORPS.

Capt. J. Y. Bogue (T.F.) to be actg. Maj. whilst specially empled. (June 29).

To be temp. Lieuts.:—L. Senécal (May 22); W. S. Grogan (May 28).

July 20.

To be actg. Lt. Cols. whilst Asst. Dirs. of Vety. Serv.:—  
Maj. E. J. Wadley, D.S.O., Capt. (temp. Maj.) E. W. Parks (T.F.), Capt. (actg. Maj.) H. C. Jagger (T.F.) (Feb. 25); Temp. Maj. J. W. F. Brittlebank, C.M.G. (June 29).

Temp. Capt. J. McC. Jamieson relinquishes his commn. on acct. of ill-health contracted on active service, and is granted the hon. rank of Capt. (July 21).

Temp. Qrmr. and Hon. Lieut. to be Hon. Capt.:—J. McNaught (July 7).

July 22.  
Capt. A. E. Webber, from E. Africa Vety. Corps, to be temp. Capt. (June 18).

To be temp. Lts.:—S. C. McKee (May 22); H. H. Wolf (May 26); T. B. Doll (June 5).

July 24.  
Capt. to be Maj.:—P. V. Beatty (Nov. 2, 1916, sen. from July 10, 1915) (substituted for notification in *Gazette*, Jan. 17, 1917).

#### TERRITORIAL FORCE, ARMY VETERINARY CORPS.

July 18.  
Capt. C. Drabble to be acting Major whilst comdg. a Veterinary Hospital (July 1).

July 22.  
Capt. P. S. Morgan to be acting Major whilst comdg. a Veterinary Hospital (July 1).

July 23.  
Sec. Lt. D. O'Kell, from Lond. R., to be Lt. (July 24).

#### The primary cause of Shock.

In an article published under this title in the *Medical Record* for June 2nd, Dr. Fenton B. Turck has summarised his extensive observations on surgical shock, and has put forward a theory as to its causation. The starting point of the author's theory is his belief that injured tissue at once begins to undergo self-digestion, leading to the production of toxic albumina which when absorbed are deadly poisons. He finds that the stomach, intestines, and liver are the organs most severely affected by these "shock poisons," and that the nervous system is not primarily involved in shock. The possibility of producing immunity against shock forms a natural development of this conception, and the author holds that a high degree of immunity can be induced by injecting into an animal repeated and increasing doses of the homologous autolysed tissue. In the course of his experimental study of shock, Dr. Turck found that the intravenous injection of peptones brought about a condition of shock similar to that following on severe wounds or mechanical injury to the tissues; the same condition was produced by the injection of autolysed muscular tissue. In one series of experiments Dr. Turck shut off a limb by elastic ligatures from the general circulation and then mechanically injured the muscles peripheral to the ligature, thereby "liberating and disintegrating cells" and permitting autolysis to occur. After a variable interval the elastic ligature was removed and the free autolysed cells and their products were allowed to enter the general circulation; this procedure promptly caused severe symptoms of shock. Shock also occurred if the autolysed muscle tissue was transplanted into another animal or if the extract of such tissue was injected into another animal. Dr. Turck's work on the possibility of producing in man immunity against wound shock is still in progress, and obviously many difficulties have to be got over before the conclusions are accepted.

#### Anærobcs in soil-infected wounds.

In the course of work for Sir David Bruce's Tetanus Committee, at the Bact. Lab., Dartford War Hospital, Mr. Henry Goodale, O. i/c., was able to collect evidence respecting anærobcs from a large number of cases. From these he states the following conclusions:—

1. That anærobcs or their spores persist in the deep tissues around bone and in scars after wounds have healed, or when they are covered with healthy granulations that give nothing but staphylococci on culture.

2. That anærobcs can find their way from an infected wound of the extremities to the serous cavities of the brain and pleura, and are found in these localities in connexion with meningitis and pleurisy.

3. The anærobcs are found in metastatic abscesses of the lung resembling in type the organisms found in the soil-infected wound of the patient, and the symptoms of these patients are those of general septicæmia.

I have not entered into any speculations as to the precise way by which anærobcs find their way from one part of the body to another; it appears certain that they produce a substance that paralyses the polymorphonuclear leucocytes and inhibits phagocytosis, this being one of the factors which accounts for the rapid progress of acute bacillary gangrene.—*The Lancet*.

#### Personal.

From *The London Gazette*, 16th July.

Master of Horses Office,  
Royal Mews, Buckingham Palace,  
12th July, 1918.

The King has been graciously pleased to appoint Mr John Willett, M.R.C.V.S., to be an Honorary Veterinary Surgeon to His Majesty.

Professor GAIGER had a successful meeting of sheep breeders at Inverness on Friday, 12th inst. The northern flockmasters are keen on the investigation of diseases. The Inverness meeting was a good hit.—*The Scottish Farmer*.

#### OBITUARY.

WILLIAM JAS. JOHNSON, M.R.C.V.S., Fountainville Av., Belfast. Graduated, Glas.: April, 1880.

Mr. Johnson died 13th July, aged 58.

Mr. GEORGE FOWLER, who practised as a Veterinary Surgeon in Aberdeen and subsequently in Glasgow, died on May 1st, aged 75 years. He took the H. & A. S. certificate in 1868.

Evidence was furnished that British pedigree stock continue to hold high favour by the prices paid at the recent sale at Chicago of Shorthorns exported from this country. The yearling bull Rodney, bred by Captain Jolliffe, of Newbus Grange, Darlington, was purchased by his exporter at the Birmingham Show and sale for 1100 gns.; at Chicago he was sold to Mr. Black, of Mansfield, Ohio, for 4000 gns.

It is stated that the seven-months-old Holstein bull, Champion Sylvia Johanna, was sold by auction on June 7th last, at Milwaukee, Wis., for 106,000 dollars (£22,000). This calf was bred at the Avondale Stock Farm, Brockville, Ontario, owned by Mr. A. C. Hardy.

Commenting on some recent big prices, the *Live Stock Journal* expresses the hope that there is some guarantee that the high prices which have been made this year are genuine, and are not faked merely to put one breed's price records in front of the other.

**"HARRY."**

I was caught in Massachusetts, I was put aboard a train,  
And unloaded at a camp near Boston Bay,  
Then they tested me for glanders, and shoved me on a  
I was treated in a most alarming way. [boat,  
I was sick, and kicked, and bitten, I was fed on foreign  
The man who waited on me was a fool; [food;  
I didn't understand it, or know the reason why;  
But I always kept my end up—as a mule.

Then they landed me in England, and stood me in the [mud;  
I was home-sick for the blue-grass and the plains.  
They put iron on my feet, and iron in my mouth,  
And they loaded me with leather, and with chains;  
I was chased with whip and rowel, until I learnt to pull,  
I was hurt, yes, hurt and frightened something cruel;  
But through my education, as the humble friend of man,  
I guess I kept my end up—as a mule.

Then I found myself in Flanders—just three years ago [to-day,  
I've worked ration dumps from "Wipers" to Peronne;  
I've been wounded twice, and have had to leave my mob,  
But, I must say, I was treated "très, très bon."  
Now I'm back at work again, yes, I'm going, thank you,  
My driver tells me I'm "a perfect fool." [strong.  
He knows that, up the line, I'll never let him down—  
That I'll always keep my end up—as a mule.

And when this war is over, and the Bosche is down and  
Will I see dear Massachusetts once again? [out,  
I guess I'm not a quitter, and I mean to see it through,  
But I'm longing for the old familiar plain.  
Yes, I mean to see the finish, if I don't go "West" before.  
On our winning, well, I'll bet the blinkin' pool.  
When you catch him, just bring Kaiser Bill to groom me  
And I'll surely keep my end up—as a mule. [once.  
"S. & S."

[The contributor who sends the foregoing, dated from a Vet. Hospital, says:—"Although it may not be quite the style of literature which you desire, we have hopes that it may at least cause a few moments relaxation to many country practitioners, after a strenuous day's work."

**Value of Milk Records.**

At the Annual General Meeting of The British Dairy Farmers' Association, held at 28 Russell Square, London, W.C., last month, a member drew attention to the great benefits he had derived from the introduction of a milk record for his herd. So greatly was he impressed with the value of milk records that he urged the Association to use its influence to make them more general, and would himself even go so far as to say that he thought it would be greatly to the benefit of this country if they were made compulsory.

Several speakers confirmed the statement that where introduced they had been found of the utmost value.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1568.

AUGUST 3, 1918.

VOL. XXXI.

## CANINE PRACTICE.

Many of us can remember the long neglect of canine practice by almost the whole of the profession in the nineteenth century, and the subsequent sudden popularisation amongst us. Some, stimulated by the success of a very few pioneers, took it up seriously before the advent of the motor; nearly all others did so afterwards. Many were forced to it by the loss in horse practice which the motor had caused them; and plenty of practices would have ceased to exist without the addition of canine work. Canine practice was a veritable godsend to the profession at that time; but many who thankfully availed themselves of it must have wondered at their long neglect of a line of work so readily available. It had been lying ready for us for decades, and we had despised it.

At present, it seems possible that some members may be tempted to again slight canine practice. It is now less profitable than it used to be, and may not improve in that respect for a long time. A stronger and more worthy reason is that most of the few veterinary surgeons remaining in civil life, especially those in the country, are now fully occupied with patients of much greater national importance than dogs. The two reasons together may lead some to neglect their canine practice; but a wiser course would be to retain what they can of it.

We are now called in to many animals whose value five years ago would not have justified veterinary treatment; and we are too few for the work. Neither the present inflated value of live stock nor the paucity of country practitioners will last for ever. Agricultural practice will retain much of the importance it has gained in the last four years, and canine practice may never again be quite so lucrative as it once was, but the latter will always be a useful adjunct. It would be well, therefore, despite the stress of other work, to neglect it as little as possible.

Canine work may again become indispensable to many practitioners; and in that case those who have continued it will follow it with better prospects than others who only take it up under compulsion.

## A BENEFACTOR.

Under the will of the late Mr. Clement Stephenson, F.R.C.V.S., the Victoria Veterinary Benevolent Fund benefits to the extent of £5000 free of legacy duty. The bequest is conditional on the Fund becoming Incorporated, and upon the benefits of the legacy being distributed in accordance with directions given. We understand that the R.V. College at Camden Town also benefits under the will.

## THE CENTRAL VETERINARY SOCIETY.

[NATIONAL V.M.A.—SOUTHERN BRANCH.]

An ordinary general meeting was held on Thursday, July 4, at 7 p.m., at 10 Red Lion Square; the President, Prof. G. H. WOOLDRIDGE, occupied the chair.

The following Fellows signed the attendance book:—Messrs. N. Almond, J. B. Buxton, W. R. Davis, A. E. Gostling, R. C. Irving, H. D. Jones, H. King, W. S. King, J. W. McIntosh, F. G. Samson, S. H. Slocock, W. N. Thompson, F. W. Willett, W. Willis, and Hugh A. MacCormack, Hon. Sec.

*Minutes.* On the motion of Mr. Slocock, supported by Mr. Irving, the minutes of the previous meeting were taken as read.

Prof. WOOLDRIDGE called attention to the fact that, in accordance with the decision of Fellows, expressed at the previous meeting, he had forwarded the resolution then passed to the Director of National Service, and received his reply, regretting that he was unable to assent to the proposal. The correspondence had already been published in *The Veterinary Record*. Subsequent to that correspondence an alteration had been made, and the resolution submitted was accordingly found to be superfluous. A new Order had been issued, exempting veterinary surgeons between the ages of 43 and 50 from being called up.

Informal discussion took place, and the consensus of opinion on the part of Fellows was favourable to the action which the Central Veterinary Society had taken.

*Correspondence.* The SECRETARY stated that he had received a letter from Mr. J. Willett, regretting his inability to attend, and at the same time acknowledging the letter of sympathy which the Society had forwarded to him on the death of his wife.

It was announced that a pamphlet had been received from the Agricultural Research Institute at Pusa, India, bearing the title: "Experiments with Emulsions for protecting Camels against attacks of Blood-sucking Flies," by H. E. Cross, M.R.C.V.S., etc.

On the motion of Mr. Almond, supported by Mr. Thompson, the Secretary was asked to acknowledge the pamphlet, with thanks.

## MORBID SPECIMENS.

Mr. H. D. JONES submitted a case of Keratoma. The horse had been lame for some time, and had been supposed to be lame from pyramidal disease. A posterior tibial neurectomy was carried out, and the horse worked sound for about two years. After the animal had been unnerved the keratoma was discovered. There was occasional suppuration accompanied by temporary lameness. An interesting point was the condition of the pedal bone—the large depression caused by the keratoma. Finally the pedal bone fractured, and the animal had to be destroyed. These tumours were more frequent than is supposed; they need careful searching for, and a large number of animals are lame from them. Extirpation is not always successful, the tumours frequently recur, and the animals often remain lame after removal.

Mr. MCINTOSH remarked that he had had two cases of Keratoma to deal with quite recently, and he had

operated successfully in both cases. The keratoma in each case was in the hind foot, a short way up from the toe. The method of removal was quite simple. He cut out a V shaped piece of horn—the point of the V being well above the keratoma—in one case extending to the coronary band, put on a “tip,” filled up the opening with dressing, and applied a blister round the coronet. After three months rest the animals were able to resume work. The horn is now perfectly sound, and there has been no recurrence of the growth.

Mr. F. W. WILLETT recalled an instance that happened three years ago, in which the horse went to work a week or ten days after operation, and had been at work ever since; at all events, nothing more was heard of the case. He had not put a blister on the coronet—it was not necessary.

The position of the keratoma in this case was in the region of the second heel nail hole on the inside of the off hind foot, which made it easy to relieve the pressure and lameness by applying a bar shoe.

Prof. WOOLDRIDGE said that he had operated as Mr. McIntosh had done for the condition under discussion. He had grooved the hoof on each side of the keratoma, leaving a space at least half an inch wide of the latter, and had stripped the horn right at the front from the toe to the coronet top, and the cases had usually been quite successful. The animals had gone to work in a month or so, with the protection afforded by the bar bandage. A little pellicle of horn always grew over the sensitive structure right away. He feared he had only been able to keep the horses under observation about a year afterwards, during which time there had been no recurrence; whether anything had happened later he could not say. His experience, however, would justify him in repeating the procedure in future cases. After thinning the wall with a rasp, he made a groove through the horn down to the sensitive laminae, and underneath to the quick of the white line. He then took hold of the protruding horn with the pincers, and stripped up from the bottom to the top. He put on a bar shoe. There was a tendency to slight hypertrophy of the laminae, owing to release of pressure. This could be controlled to some extent by a tightly rolled pad of tow or wool bandaged firmly in. There was no need to wait for the horn to grow down before sending the horse to work; the animal would have a groove down the front of the foot, but could work soundly.

Mr. F. W. WILLETT introduced a case of rupture of the rectum in a mare in service. The mare was still living six weeks after the occurrence, and was seen by Mr. Slocock and himself just before it was destroyed. He had seen the mare three or four times, and had no idea of the rupture: being on grass, and the bowels relaxed, there was no indication of the trouble. The animal had fallen away considerably, and when the speaker first saw her she had a slight discharge from the eyes and nose, which suggested a chill and debility. He had watched her on one occasion for some time and noticed that she crouched now and then and lifted her hind legs as though in abdominal pain. He suggested to the owner that the mare was colicky, and enquired whether she had been so before; whereupon the owner stated that he had noticed the condition previously. The speaker then made a rectal examination and found the rupture. The owner then remembered that five or six weeks earlier the stallion which served the mare had penetrated the rectum. The owner stated, however, that there was very little bleeding. She was subsequently properly served, and nothing further thought of the matter; the mare had continued to work. It would be seen that the peritoneal coats of the bowel were congested, and there were several abscesses.

Prof. WOOLDRIDGE asked whether any Fellows had had experience of rupture of the rectum during proper service *per vaginam*. Such ruptures were said to occur

in cases where the rectum was full of faeces. [Mr. Irving remarked that while he had heard of such cases, he had not met any].

Mr. SLOCOCK could not believe that rupture would occur in service other than into the rectum. He had seen the mare referred to, in company with Mr. Willett. The mare was wasting, and he was willing to believe that six weeks before she had been in quite big condition. The mare drank a little from the water trough, but showed no abdominal pain, or any symptoms attracting attention to that part. On passing his hand into the rectum, he found distinct stricture and evidence of rupture right at the roof, about a foot in. The faeces were semi-fluid. He did not know whether they might have strained through the small orifices by constriction. The mare then evinced considerable pain and crouched, but he believed the pains would only exist at times of defaecation or attempted defaecation. He assumed that the horse was not much bigger than the mare; otherwise he did not think the rupture would have been so much at the roof. Had it not been for the distinct stricture of the intestine he would have thought there was a chance of recovery; as it was she was useless. He did not accept the opinion that the responsibility rested with the owner of the stallion for improper service.

General discussion ensued on the question of responsibility, Mr. Irving contending that proved negligence would entail this. Mr. Slocock argued that it was difficult to determine negligence, which might be attributable to the man with the mare or the man with the stallion; the question was not one of control. Mr. Irving—A stallion entering the rectum of the mare would get twisted, and be out of control. Prof. Wooldridge said that, at the actual time of service, the passage of the penis should be observed by some competent person, and the provision of such an attendant was a responsibility of the owner of the horse. Mr. McIntosh believed Mr. Davis's view to be correct. He further believed that in an action for improper service judgment went against the owner of the stallion. He thought the owner of the stallion would certainly be liable if improper service were proved; such as service per rectum. Mr. Davis believed that in the case referred to by himself and Mr. McIntosh the evidence showed that the service was correct, but rupture was caused by the presence of a mass of hard faeces. In answer to Prof. Wooldridge Mr. Willett stated that the post-mortem revealed no faeces in the peritoneal or pelvic cavity; the rupture was partial, not complete, being only at the roof, a fact which kept the faeces from passing through the rent.

### ACNE AND IMPETIGO.

By PROF. G. H. WOOLDRIDGE, R.V.C., LOND.

These two diseases of the skin are included in the term *Ecthyma*, which may be defined as a localised dermatitis characterised by the formation of pustules, which may be superficial in character, or deep-seated and result in some loss of structure.

### ACNE, PIMPLES, BOILS, FURUNCULUS.

Acne is a folliculitis of the skin, *i.e.*, an inflammation of the hair follicles or the sebaceous glands, resulting in the formation of pustules. The lesions are circumscribed and may be comparatively superficial as in *pimples* or they may be deep-seated, involving the deeper structures of the skin. When the latter lesions are single or isolated they are called *boils*; when they are small and appear in crops they are called *furuncles*. Acne is generally due to the entrance of pyogenic organisms which have gained access through the orifices of the skin or into the hair follicles as the result of rubbing. In fact it may be regarded as a “rubbed-in” dis-

case; consequently it is met with mainly in those parts of the body which are exposed to rubbing by harness and other objects. In this way it may be met with as a complication in strangles in horses. It may also be brought about by the choking up of the ducts of sebaceous glands.

A lesion practically indistinguishable from acne may also be brought about by biting flies. Another smaller pustular eruption may be produced by the application of certain medicaments, such as iodine, tar, vaseline and other chemical irritants. In these instances the lesions are variously due to choking up of the glandular ducts, or to chemical irritation, or both. The lesion set up by the invasion of the skin by the parasite *demodex folliculorum* accompanied by staphylococci in any species is a form of acne. Acne appears to be more frequent in the spring and summer than in cold weather. All species of animals are susceptible, but it is most frequently met with in horses, sheep and dogs.

**Symptoms.** The lesions may occur in any part of the body, but, as already indicated, they are most likely, in horses, to be met with under the collar, saddle, or along the sides, or at any place that may be rubbed by the harness. In the dog, the lesions are frequent about the head and under the abdomen, while in sheep they are principally found inside the elbows and thighs.

In simple acne (pimples) the pustules are very small and rarely exceed the size of a lentil. If examined early the lesions may be felt as small elevations, which in a day or two become pointed and contain a small amount of pus-like material. They are usually numerous and are painful, but are not invariably so, and the skin carrying them can be freely moved about over the subcutaneous tissues.

In the more severe form (boils and furuncles) the lesions are deeper seated and may involve the whole structure of the skin. They are hot and painful, and surrounded by a zone of hyperæmia. The affected animal resents manipulation of the part, and horses will cringe away when the part is approached, even before it is touched. The lesion cannot usually be moved about so freely on the underlying structures. When mature it has a yellow point in the centre which bursts, giving exit to pus; sometimes there is a small necrotic core. At other times the painful lesion appears to subside without pointing or bursting (blind boil). Boils or furuncles under the collar in a horse may cause the animal to become a jibber.

The duration of the lesions depends upon the depth of skin involved. In the superficial form it may only last a few days or a week, while in the deep seated form it may be two or three weeks before recovery occurs. During this time other lesions may crop up, so that the affection may become prolonged. Healing in the deep-seated form leaves a more or less permanent mark which may be attended with loss of hair or a change in its colour.

In folliculitis due to blocking of the sebaceous glands, an accumulation of curdy material takes place and causes a local swelling, which may vary from the size of a pea to a pullet's egg. These are called *sebaceous cysts*, or comedones. The walls of these cysts may actually degenerate and calcify and are then easily dissected out.

Except in very severe cases acne does not set up systemic symptoms.

**Contagious Acne.** A variety of acne in the horse is undoubtedly contagious and is due to the *Preis-Nocard bacillus*. It is often called American skin disease. This also occurs in two forms—superficial and deep. In the former the lesions are very numerous, occurring chiefly on the shoulders and sides. They are very superficial, practically painless, and do not leave any permanent marking. There is a great disposition to spread all over the surface of the body of the affected

horse, and to other horses, by means of grooming utensils, rugs, harness, etc. This affection is said to have been introduced into England with Canadian horses in 1879, but it was already in existence on the Continent of Europe before that date.

A much more severe form occurred in Great Britain in 1913-14, and was also said to have been introduced from the American continent. In this outbreak the lesions were less numerous, but more deep-seated, very painful, and not nearly so amenable to treatment. I observed numerous cases in which the affection lasted for months, and not infrequently animals affected had to be destroyed.

*In sheep*, the lesions of ecthyma occur commonly in the parts devoid of wool, such as inside the thighs and elbows. They are pointed and contain pus, but unless very numerous cause very little systemic disturbance. Occasionally lesions of acne are met with along the middle of the back, and the fleece of that part is ragged and torn. This is not infrequently due to the use of a too irritant sheep dip; and care should be taken to avoid confusing it with sheep scab. It is common to find several sheep simultaneously affected, but there is no direct evidence of contagion.

*In swine* the lesions of acne are usually black spots, and are due to *demodex folliculorum* or to inturned hairs.

**Treatment: horses.** In the superficial diffuse form, the skin should first be soaked with a hot solution of sodium carbonate, to soften the epithelium to allow the subsequent dressings to penetrate better. The condition then yields readily to the application of simple disinfectants, such as 2% creolin solution; ol. picis  $\mathfrak{z}$ i, ol. rapi  $\mathfrak{z}$ x; ung. salicylici 1:20; or sulphur liniment (sulph. sub.  $\mathfrak{z}$ ii, potass. carb.  $\mathfrak{z}$ i, ol. picis  $\mathfrak{z}$ i, ol. rapi  $\mathfrak{z}$ x).

In the more severe forms as in boils, local pain must be reduced by hot fomentations such as hot water, or antiseptic poultices, and when mature the boil should be lanced with a crucial incision and its contents—pus or necrotic core—removed. It must then be treated with a strong disinfectant as a first dressing, such as pure phenol, or tincture of iodine; and subsequently treated as a simple wound. The phenol is very conveniently applied by dipping a probe or small grooved director into it and inserting the point into the centre of the lesion. It frequently happens in horses that after such a lesion has completely healed there remains for a considerable time some irritability of the part such as may actually cause lameness if under the collar.

In the severe form of contagious acne good results are very difficult to obtain. In such cases an autogenous vaccine may be tried. Internally a course of tonics should be prescribed, such as arsenic, iron, strychnine, quinine, and sulphur. Thorough disinfection of harness, clothing and grooming utensils should be carried out, and also the stable and any places where the animal may have rubbed, such as shafts, etc. When the contagious variety is suspected isolation should be practised. Affected horses should not be worked, but daily exercise should be given.

*In dogs* the treatment of the condition is very similar to that of horses, but the tar preparations must be used with caution, owing to their toxicity for dogs. Salicylic preparations 1:20 are very serviceable, as also are Chinisol 1:500, and Eusol (0.5% hypochlorous acid). Internally, a course of tonics should be prescribed, such as arsenic, or a mixture of Cod-liver oil, Liq. extract of Malt and Syr. ferri phos. Co. The acne lesions of follicular mange in dogs generally yield readily to autogenous vaccines.

In all species small impacted sebaceous glands may be relieved by puncture and squeezing, but the larger ones should be dissected out, otherwise they are likely to recur.

*In sheep* with acne, a local application of carbolic lotion, or sulphur dressings should be resorted to, and internally a small dose of a saline administered and followed by a course of tonics.

#### IMPETIGO.

Impetigo is an eruption of the skin consisting of a superficial pustule, often accompanied by a surrounding zone of hyperæmia. The lesions are usually painless, and often termed 'cold pustule' in contradistinction to acne, the lesions of which are often called "hot pustules." The lesions in impetigo are always due to a micrococcus, but the condition is generally met with in animals with vitality reduced from various causes. It may thus be met with in puppies at the time of teething, and also the subject of worms. In bitches it commonly occurs about the time of parturition and when rearing puppies. A lesion practically indistinguishable from impetigo is also met with in the so-called cutaneous form of distemper. In milch cattle impetigo is frequently met with affecting the skin of the udder immediately after calving, particularly in highly fed cows. This form often assumes a contagious character and has been mistaken for vaccinia.

Impetigo is also met with occasionally in horses and in swine, but more rarely than in dogs and cattle. By some authorities impetigo is regarded, somewhat questionably, as the pustular form of eczema (*E. impetiginoides*).

**Symptoms.** The lesion consists of a flat, very superficial pustule, which may be preceded by a tiny vesicle under the epidermis. The surface is yellow and soft. Generally the lesions are circular and discrete, and from a quarter of an inch to half an inch in diameter, but, if numerous, they may be confluent. They are usually free from irritation, and are often surrounded by a red zone. They rupture quickly, and form yellow crusts which soon fall off. Sometimes the hair over the part is matted, as the result of which irritation may arise. When the lesion occurs on the hairless parts, it frequently leaves on bursting a simple ragged edge of epithelium, and the previous existence of the pustule may be indicated by a spot which is slightly clearer than the surrounding area, and the margin of which appears as though etched out. Impetigo always runs a rapid course, and this fact together with the absence of irritation serves to distinguish it from eczema.

**Treatment.** Impetigo is amenable to very simple measures. Internally a course of tonics should be prescribed, while locally the scabs should be removed by fomentation with a mild antiseptic and astringent lotion, such as Chinisol (1-500), Eusol, Carbolic acid 1%, creolin 1%. Subsequently a mild dusting powder, as boracic and starch, may be applied.

*In cows* the coal tar preparations and eusol should be avoided, owing to the danger of tainting the milk. Chinisol Lotion or boracic acid are preferable.

#### DISCUSSION.

Mr. H. D. JONES remarked that his experience of acne in the horse was chiefly with one class—the carriage horse. Usually the trouble occurred at one period of the year, when the horses were first clipped. Presumably the skin was then tender and more liable to infection. A day or two after clipping pustules appear, frequently under seat of harness; and he believed that the acne was also to be attributed to the pressure of the rugs, two or three in some cases, which were put on the animals. He had known of horses that were covered all over with the pustules, and had temperatures of 104° and 105°; in some cases the trouble was so acute that the animal required prolonged treatment. In treatment he advocated the disuse of rugs and the avoidance of grooming. A little antiseptic ointment should be ap-

plied to the skin, and animal kept in warm stable and fed on suitable diet.

Mr. W. R. DAVIS said that the nomenclature of skin diseases was a source of trouble to him; he was unable readily to differentiate the cases. He would ask the President how he would class the boils on the udders of cows—as impetigo or acne? Sometimes these contained as much as a tablespoonful of pus. They were superficial, and did not affect the parenchyma of the gland. They required very little treatment, but were allowed to burst of themselves in many instances. They were sore, and often caused the cow to kick when milked. They were quite common.

Mr. THOMPSON had seen different forms of acne in the horse at different times of the year. The eruptions were often noticeable at the top of the neck if the animal's hair was taken off, as used to be customary, but were less frequently seen now, except in the case of hogged-maned horses. He had the impression that the trouble was due to irritation of the hair follicles by the collar riding on the hair. Occasionally there was an isolated acne pustule, which was easy to deal with. He had known instances in which such pustules, being broken by the collar and consequently discharging, had led to prosecution. He usually lanced them and introduced carbolic, which soon remedied the trouble. In cases where there was a continuous crop of such pustules, he had found it best to treat internally with arsenic, and a blister of biniodide of mercury, and invariably with success. Impetigo was common where clipped horses were out in a shower of rain, and it occurred especially where the breech straps crossed the hind quarters, due, possibly, to some irritant washed out of the leather. He generally used a cooling lotion, such as lead and zinc, or sulphur dressing.

Mr. McINTOSH shared with Mr. Davis the difficulty in differentiating, scientifically at all events, between certain skin diseases, as many of these present the most varied pathological characters. His experience of Acne was not a large one. He had now and again a case to deal with, and as a rule he started off by giving the animal a dose of physic followed by blood tonics. Many of these cases, however, were extremely troublesome and required considerable surgical attention, opening the pustules freely, pressing out the contents, and the subsequent use of disinfectants, or cauterisation if necessary. Total extirpation of the affected parts may be the only remedy.

Quite recently the speaker had a case of skin disease in a white skinned animal which he was unable to classify with any degree of certainty. He would endeavour to give them a description of the symptoms, and perhaps the Fellows would be able to relegate the disease to its proper division.

The animal—a harness mare—of the under-bred type got down in condition and was unthrifty looking. It was thrown off work, and beyond generous feeding nothing was done in the way of treatment until some ten days afterwards, when well-defined raised swellings of the skin appeared pretty well all over the body, resembling nettle rash. These swellings were quite hard and painless, and remained in this condition for weeks. Further than this, there appeared little constitutional disturbance, as the temperature and pulse remained normal, and the appetite, although fickle, was quite good. Treatment consisted of physic and blood medicines, and the application of oil and lard to the skin. It took, however, several weeks before these nodules showed any tendency to disappear—a few showed a slight weep from the surface. Eventually the whole cleared off in the form of scales, leaving distinct markings all over the body, which ultimately got covered over with a beautiful coat. One of the sequelæ was loss of sight in both eyes.

Prof. WOOLDRIDGE replied. He had rather expected reference to be made to the usefulness or otherwise of autogenous vaccines. This method of treatment, while likely in some instances to be extremely useful, was liable to a bad reputation from the fact that it was used for all and sundry cases. The principle of autogenous vaccination had met with greater success in skin diseases than in anything else due to the streptococcus, and particularly the staphylococcus; he thought the practice might be more frequently resorted to in skin diseases which resulted from pus-producing organisms. He had also anticipated some reference to follicular mange. He did not suggest that follicular mange was due to pus-producing organisms, but the pustular lesions of follicular mange were; and autogenous vaccination afforded relief.

He noticed that others, like himself, had found difficulty in making a differential diagnosis in some of these cases, and, so far as treatment was concerned this was not important. What was of importance was the prognosis and the possibility of contagion. It was, moreover, well to know whether the case would be of long or of short duration. Without being able to foretell absolutely, a more correct opinion would probably be given if a differential diagnosis could be made. It was not always easy to distinguish between contagious and non-contagious trouble. In the case of a disease produced by organisms, there was always the possibility of its being transferred, more readily in some cases than in others. In the majority of instances simple acne was not very readily transferred, and, as a rule, the infective matter had not only to be spread on the skin of the new animal, but to be planted under the epithelium. That was an important feature to remember, and was largely responsible for the instances of breaking out after clipping. He believed that in these instances the cause was a slight scratch, invisible at the time of clipping, which became infected with pus-producing organisms, as a result of which acne pustules were produced in two or three days, which, however, passed away a few days later without special treatment. The point had been referred to by Mr. Jones and Mr. McIntosh.

Mr. Davis had quoted cases that had occurred on the udders of cattle, where a lesion on bursting emitted as much as a tablespoonful of pus. The speaker did not think that such cases should be regarded as either acne or impetigo; simply superficial abscesses.

[Mr. Davis: These formations are small, and in the nature of boils; they come in groups; are not of traumatic origin; and are subcutaneous.]

Prof. Wooldridge admitted that the line of demarcation was narrow, and it was difficult to say where a boil ended and an abscess began: a boil is actually a small abscess, and a pustule is a miniature abscess. In view of the quantity of pus, he would rather regard the formations as abscesses than as acne or impetigo.

Mr. Thompson had referred to certain troublesome cases occurring at the top of the neck and at the sides.

The speaker had thought Mr. Thompson was about to refer to botryomycosis in that region; cases in which a series of small bursting points occurred, about the size of the top of a finger. These were very painful, and difficult to treat satisfactorily. He believed the only course was to make a diagnosis by microscopic examination of the pus. A red blister would sometimes produce improvement, but the trouble recurred. In these cases autogenous vaccination was of no use, and he could only advise destruction of the horse.

[Mr. Thompson had seen horses relieved and at work—with further trouble ensuing. To which Prof. Wooldridge replied that the cases were probably acne and botryomycosis.]

Responding to a further statement by Mr. Thompson, that the spots had occurred on the side and on the top

of the ribs, Prof. Wooldridge regarded these as acne produced one after another by infective material being carried along, precisely as a series of pimples on the forehead under the brim of one's hat; one would burst, leaving infective material on the hat, which might be rubbed in at some other place.

Mr. McIntosh's reference to the case of skin eruptions and subsequent blindness of the animal was of very great interest. He would not have regarded that trouble as primarily a skin disease, but a systemic disease in which skin lesions occurred—in all probability a form of pyæmia, the blood stream becoming infected, due to abscess, with organisms carried to the eye as well as to the skin. That was, he should say, the cause of the damage to the eyeball, which resulted in blindness. It was possible to get organisms widely distributed in the blood without proving fatal, and he would think the case quoted by Mr. McIntosh to be one of these.

[Mr. McIntosh asked whether Prof. Wooldridge would describe as simple acne cases of slight swellings under harness, etc., which arose after a wet day and disappeared in a day or two. Prof. Wooldridge said he would consider these as cases of localised erythema.]

Mr. MCINTOSH proposed a vote of thanks to the President, the meeting being the last of the session—a session of which Prof. Wooldridge might well feel proud. He (Mr. McIntosh) had seconded his nomination to the chair, and while it was not usual for the Society to elect a President for the second term, it was felt that under existing conditions the election of a new Fellow of the Society as President would have imposed a difficult task upon such Fellow. Prof. Wooldridge was already a tried man, and had reason to be gratified at the attentances he had secured—the times being considered—and the useful work done in matters of national and professional importance. He formally proposed a vote of thanks to the President.

Mr. SAMSON seconded the vote, and thoroughly endorsed the remarks of the previous speaker.

The vote was put to the meeting and carried with acclamation.

Prof. WOOLDRIDGE, in returning thanks for the vote, also thanked the members for their attendance at such a time of stress, when it was particularly difficult to find time. It was a great pleasure to him, because it afforded relaxation from other things, and because he believed it to be an advantage to meet, if only once in two months. He agreed with Mr. McIntosh that the Society had done good and useful work; in particular, the work relating to the feeding of horses of itself justified "carrying on" during the past session.

Mr. ALMOND then proposed a vote of thanks to the gentlemen who had provided morbid specimens for discussion at the meetings. The Society was much indebted to those who, in that way, had provided matter of both utility and interest.

Mr. DAVIS seconded the vote, which, on being put to the meeting, was carried with acclamation.

The PRESIDENT then announced that the next meeting would take place on the first Thursday in October.

HUGH A. MACCORMACK, Hon. Sec.

#### HIGH VALUES OF BREEDING STOCK.

The sales of breeding stock at Sudbourne, Sussex, last week included a Suffolk stallion at 2000 gs., and a mare at 900 gs. The ninety-eight horses sold brought a total of 31,600 gs.

For the Large Black pigs 455, 300, and 250 gs. was paid for sows, and 315 gs. for a boar. The 144 lots sold averaged £42 15s.—a higher average and a larger number of lots than any previous sale of pigs.

**COAL-TAR IN THE TREATMENT OF SORES.**

For the treatment of sores in horses and other large animals, Bringard uses coal-tar. To a kilogramme of this, when warm, he adds 200 grammes of calcium chloride and 100 grammes of boric acid. The sore, freed from foreign bodies and washed with tepid physiological solution, is covered with this adhesive mixture by means of a spatula.

**THE TREATMENT OF EQUINE LAMINITIS.**

Hinniger has published an article upon this subject in the *Schweizer Archiv. für Tierheilkunde* for 1917. He has obtained good results from the use of Fallianine; but latterly he has adopted another treatment with results that surpassed his expectations. This consists in bleeding, and then injecting a litre (= about 1½ pints) of a 2½ per cent. aqueous solution of sodium bicarbonate into the jugular. In less than twenty-four hours, this treatment is followed by a very great improvement.—(*La Clinica Veterinaria*).

**SUBSCRIPTIONS TO R.C.V.S.**

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

J. W. Baxter, London	£1	1	0
W. W. H. Edwards, Ludlow	1	1	0
Wm. Kennedy, D.S.O., Maj. E.A.V.C.			
Difference of exchange on draft of £21 from East Africa Veterinary Officers	2	12	6
J. Mosedale, Morristown, N.J., U.S.A.	1	1	0
A. O'Neill, Capt. A.V.C.	1	1	0
Edward Sewell, M.C., Capt. A.V.C.			
(1914-15-16-17-18)	5	5	0

**ARMY VETERINARY SERVICE**

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, July 25.

**REGULAR FORCES. ARMY VETERINARY CORPS.**

Temp. Lieut. to be temp. Capt.:—N. Fraser (June 6).

July 27.

Capt. H. E. Cross, Ind. Army Res. of Off., to be temp. Capt. (July 3, sen. June 15, 1917).

July 29.

Capt. W. H. Simpson relinquishes the actg. rank of Lt.-Col. on ceasing to be specially empld. (July 8).

Temp. Capt. M. P. Hatch relinquishes his commn. on account of ill-health contracted on active service, and is granted the hon. rank of Capt. (July 30).

Late temp. Lieut. to be temp. Capt.:—J. J. McGrath (July 11).

Temp. Hon. Lt. G. C. R. Thorp relinquishes his commn. on acct. of ill-health, and retains the hon. rank of Lt. (July 30).

To be temp. Lt.:—W. Ledger (July 11).

Temp. Maj. T. C. Evans, M.C., Can. A.V.C., is seconded for duty with the War Office (June 18).

**SPECIAL RESERVE OF OFFICERS.**

Hon. Capt. to be Capt.:—G. Barnett (July 22).

**Personal.**

Lieut.-Colonel T. B. WOLSTENHOLME, R.A.M.C. (T.), of Urmston, Manchester, has recently been awarded the Croix de Guerre; he is son of Jno. B. Wolstenholme, F.R.C.V.S., of Manchester.

**OBITUARY.**

FRANK HENSON GIBBINGS, F.R.C.V.S., Black Boy Hotel, Nottingham. Graduated, Lond: Jan., 1878.

Mr. Gibbings died July 27th, aged 63 years.

**SPECIFIC PARAPLEGIA IN BOVINES.**

Dear Sir,—I was very much interested in Mr. William Scott's article on "Specific Paraplegia in Bovines—a new (?) disease," as a disease with similar symptoms affected a large number of cattle in the district in which I happened to be during the months of January and February, 1917.

About 50 cattle died in about six villages; no less than about 30 dying in one herd, including two yearling bulls.

B.E.F.

G. REES-MOGG, Major A.V.C.

**Chemists and Veterinary prescribing.**

At the Seventeenth Annual Meeting of the Chemists' Defence Association at the Holborn Restaurant, London, on July 11, the Chairman of Directors, Mr. P. F. Rowsell, presided. In the course of his address he referred at considerable length to discussions which had arisen respecting the new Veterinary Section established in January this year, and of which full particulars were published in the *Anti-Cutting Record*. Two hundred and fifty members of the Association had joined the new section, and already one member had reaped the advantage of it. This member had supplied a strong ointment to cure warts on a heifer, and unfortunately its use had resulted in the death of the animal and the subsequent payment of £7 compensation to the farmer. This amount had been refunded to the member by the C.D.A.

He gave another instance of a veterinary claim, showing the necessity for members to take advantage of the new section. It happened quite recently in a large city. An owner of a bull pup bought Easton's Syrup from a chemist and gave it in nine-drop doses to the dog, which very soon succumbed to strychnine poisoning. The angry owner accused the chemist of supplying wrong medicine, and talked of compensation and made various threats. As the member had supplied what was asked for without recommendation or comment, and as the syrup was found by analysis to be of correct composition, he was recommended by the C.D.A. to resist the claim.

He described an interview which he and the Secretary had had with a well attended meeting of the East Anglia Federation of Pharmaceutical Associations and a similar meeting of the Essex Association of Pharmacists which the Secretary had attended, at which the subject of veterinary risks was discussed at great length. These bodies considered that veterinary risks should be included

in the general subscription, even although that might have to be advanced a little. He had pleasure in informing them that the Directors had again considered the subject, and that they had unanimously come to the conclusion that something of the nature indicated would be attempted before the Association was very much older.

The probable risks could be gauged by a full year's experience with 250 Veterinary Section members. He recommended that, as veterinary risks up to £100 could be covered for 7s. 6d. a year under the new section, it was to the advantage of all specially concerned to join that in the meantime. He stated emphatically that the Directors intended to give the new section a fair trial.

Mr. Lloyd described a case in which he had been accused of being the unwitting cause of the death of a prize canary, and his customer talked big about £100 compensation. Acting on advice he received from the Association, he resisted the claim and heard no more of it.

Mr. Rowsell explained that the Association had always given free legal advice in regard to veterinary mishaps in their member's shops, but they did not pay compensation except to those who were members of the section.—*The Pharmaceutical Journal*.

*Treas:* Mr. J. F. Healy, M.R.C.V.S., Midleton

**CONNAUGHT V.M.A.**

*Pres.* Mr. D. Hamilton, M.R.C.V.S., Ballina  
*Hon. Sec. & Treas.* Mr. A. J. Moffett, M.R.C.V.S., Galway

**VET. MED. ASSN. OF IRELAND.**

*Pres:* Prof. J. J. O'Connor, M.R.C.V.S., R.V. Coll., Dublin  
*Hon. Sec:* Prof. J. J. O'Connor.  
*Hon. Treas:* Prof. J. F. Craig, M.A., M.R.C.V.S.,  
 R.V. Coll., Dublin

**NORTH OF IRELAND V.M.A.**

*Pres:* Mr. J. Ewing Johnston, M.R.C.V.S., Belfast  
*Hon. Sec:* Mr. P. Walsh, M.R.C.V.S., Magherafelt  
*Hon. Treas:* Mr. Howard McConnell, M.R.C.V.S., Armagh

**THE VETERINARY OFFICERS ASSOCIATION FOR IRELAND.**

*Pres:* Mr. F. W. Emery, F.R.C.V.S., Dublin  
*Hon. Sec:* Mr. T. McGuinness, B.A., M.R.C.V.S.,  
 36 Mount Charles, Belfast  
*Hon. Treas:* Mr. Hannan, M.R.C.V.S.

**Scottish Branch:**

*Pres.* Dr. O. Charnock Bradley,  
 Ryl. (Dick) Vet. Coll: Edinburgh  
*Hon. Sec.* Prof. A. Gofton, Municipal Buildings, Edin.  
 (on Service).

**NORTH OF SCOTLAND V.M.S.**

*Pres:* Mr. W. Brown, M.R.C.V.S., Marischal Coll: Aberdeen  
*Hon. Sec. & Treas:* Mr. G. Howie, M.R.C.V.S., Alford, Aberdeen  
*Meetings,* Last Saturday in January and August

**ROYAL SCOTTISH V.S.**

*Pres:* Mr. Reid, M.R.C.V.S., Auchtermuchty.

**SCOTTISH METROPOLITAN V.M.S.**

*Pres:* Mr. J. Riddoch, M.R.C.V.S., Edinburgh  
*Hon. Sec. & Treas:* Mr. Jas. Henderson, M.R.C.V.S.,  
 Public Health Dept., City Chambers, Edinburgh

**WEST OF SCOTLAND V.M.A.**

*Pres:* Prof. John R. McCall, M.R.C.V.S., Vety. Coll. Glasgow  
 (on Service).  
*Hon. Sec:* Mr. J. F. Macintyre, M.R.C.V.S.,  
 19 Bank Street, Hillhead, Glasgow  
*Hon. Treas:* Mr. Geo. W. Weir, M.R.C.V.S.,  
 88 Crookston Street, Glasgow  
*Meetings,* Second Wednesday, May, Oct. and January

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1570.

AUGUST 10, 1918.

VOL. XXXI.

## FEES AND CHARGES.

The increased cost of living and travelling, and the general rise in the remuneration for work of almost every description, have forced upon practitioners the necessity for a revision of fees. Most of these reasons, of course, have appeared comparatively recently; but they are certain to remain in action for a long time. Those whose memories cover two or three decades of veterinary practice can recollect other changes bearing upon remuneration, for the most part older in standing and slower in development, which have taken place in it. Broadly speaking, our fees and charges have not changed greatly during the last generation; but our work has undergone alterations which have affected them considerably in the direction of necessitating a revision.

Formerly many veterinary surgeons profited largely by the sale of medicines, especially stock medicines in quantity. There were men, mostly in the country, who were really much more medicine vendors than practitioners. For various reasons, this source of income has declined for many years; and there is no probability that it will ever again approach its old level. Something like this might also be said of shoeing forges, which, though still considered indispensable in some practices, are not nearly so important as in old days. On the other hand, there has been a great increase in such special work as inspections, and diagnostic and preventive inoculations. It may be said generally that veterinary work is now much more strictly professional, requiring the personal attention of the practitioner himself, than it used to be, and that the element of trade is every year becoming a less important attribute. Our professional fees have never been very high, and on the whole have not risen much, while our trade profits have diminished. The numerical increase in the former has not compensated for our loss in the latter.

This broad consideration should be kept in mind in connection with the revision of fees. Many other points of general application may arise, which should also be remembered. One is the longer journeys which we habitually undertake in these days of the motor; another, which will gain in importance in the next few years, is the varying economic value of the different branches of our work. The last point is one on which clients may have a good deal to say; and here it may be said definitely that we are not likely to effect much improvement in our remuneration, unless we are prepared to look at the question fairly from the client's point of view as well as from our own.

## "UNUSUAL."

*Case I.* Saturday, July 13, 1918. Cow straining, and some discharge from vagina. Due to calve on the 18th.

I was asked to see her on the 16th. I could pass two fingers into the os uteri—but no more. On the 18th one hind foot and fetlock was just in the vagina.

The next day, I was only just able to get my hand into the uterus and bring forward the other hind foot, which was forwardly placed, showing hock presentation. Delivery took place with help, and recovery followed. Of course, the calf was dead.

*Case II.* Sunday, July 14. Cow straining, and some discharge.

I saw her for the first time the next evening, very late. Torsion of the uterus suspected, but was left to "wait and see."

On the 17th she was cast and repeatedly turned over; but without avail. She was slaughtered the same evening, and an interesting post-mortem revealed torsion of the uterus. It may be interesting to state that in spite of the stricture it was just possible to pass the ends of two fingers through and feel the calf's hoofs.

*Case III.* Sunday afternoon, June 14. Cow with discharge in the morning.

Saw her at 5.30 p.m. Down, and unable to rise. Head under manger; excitement very marked. Examination per vagina revealed the os slightly open, and two or three fingers could reach the feet of the fetus. There was a distinct curve in the neck. She was not due to calve until the middle of September.

I was obliged to return home for the udder syringe, as the symptoms were those of drop. On getting back to the case, which was about nine miles from my house, I found the cow in a state of complete coma. I injected, or inflated, the udder, packed her up, tying the teats with tape. She recovered about 1.30 a.m. next morning, and during the day aborted, but made a complete recovery.

W. W.

## GENTIAN VIOLET IN JOINT INFECTIONS.

In the *Journal of the American Medical Association* for April 13th Dr. John W. Churchman, professor of surgery in Yale University, describes the treatment of infected joints by lavage and direct application of a 1 per mil. solution of gentian violet, which has proved most effective in his hands. The method is now being studied by the author in parasitic skin diseases.

## ABSTRACTS FROM FOREIGN JOURNALS.

CAUTERISATION OF THE BUCCAL MUCOUS  
MEMBRANE BY CHLORAL HYDRATE.

Fröhner records this case in the *Monatschrift für praktische Tierheilkunde*. A horse was attacked by colic and, by a veterinary prescription, chloral hydrate was administered in the concentration of one part to six parts of liquid (extract of aloes, ether, and alcohol). A croupous stomatitis was produced. Fröhner, examining the case, observed abundant salivation, painful swelling and formation of crusts in the skin in contiguity with the mouth, great tumefaction, yellowish colour and acute pain of the buccal mucous membrane (especially in the region of the bit), and diphtheritic layers of the length of the hand in the tongue, with ulcerations of the diameter of a cent. Treatment with aluminium acetate produced recovery in five days. Fortunately the horse had not swallowed the solution of chloral; if it had done so, a corrosive gastroenteritis would have been produced. Fröhner believes that some of the hæmorrhagico-diphtheritic inflammations of the whole digestive tube, the etiology of which remains obscure, are due to the improper administration of chloral hydrate. This drug, therefore, should always be well diluted or joined to a mucilaginous substance.—(*Revista Veterinaria de Espana*).

## INTRADERMIC TEST FOR THE BACILLUS PULLORUM.

In Bulletin No. 517 of the Bureau of Animal Industry of the United States Department of Agriculture, Archibald, Ward, Bernard, and Gallagher give an account of work they have carried out to find a diagnostic test for the presence of the *bacillus pullorum* in birds.

The *B. pullorum* is one of the occasional germs of white diarrhoea in chickens; amongst which it causes enormous losses. It becomes localised in the hens, which are the chief reservoirs of the disease, and it is one of the microbes most frequently found in eggs; the infection may thus be borne to many distant places.

The conclusions of the authors' work are as follows:—A dead culture of the *B. pullorum*, after having germinated for about a month, and without any treatment but the addition of carbolic acid, has given the most satisfactory results.

It appears that the inflammation or oedematous tumefaction following the inoculation of this product into the wattles, when observed at a definite interval of time, is an indication of the presence of the *B. pullorum* in the fowl submitted to the test. The authors' experience leads them to the conclusion that an interval of twenty-four hours gives the best results; but it would be well to test, in a large number of birds, whether a slightly longer interval might be preferable.

The results indicate that any perceptible enlargement of the wattle may be considered significant. A second intradermic test, made after an

interval of four days, gives results which vary little from those of the first test. Other tests, practised at intervals of two months, give less exact results. There is, therefore, no advantage in repeating the tests.

Of birds artificially infected and tested in the laboratory, 90 p.c. gave positive reactions. In 6 p.c. the tests failed; not giving any reaction, although lesions were observed. In 3 p.c. there were neither reactions nor lesions.

In one experiment with 231 birds, in which the agglutination and the intradermic tests were employed simultaneously, the intradermic test in one instance failed after an interval of thirty-eight hours to reveal a case given as positive by the other reaction. In another lot of 50 birds, in which the same comparative test was made, the intradermic test, examined after an interval of thirty-six hours, failed to reveal a case which had reacted positively to the agglutination test.

Of 47 birds which were examined by the agglutination test, 40 gave positive reactions, and the other seven doubtful ones, resulting in a complete agreement between the agglutination and intradermic tests and with the post-mortem findings in 70 p.c. of the cases.

Only in 72 p.c. of the birds naturally infected and which had reacted to one or both tests were the post-mortem findings positive.

The authors' conclusion is that the intradermic test has succeeded sufficiently well to guarantee it a more extensive trial in practice in comparison with the agglutination test.

## "REMOUNTS," AND HORSE-TRANSPORT AT SEA

In purchasing large numbers of horses in order to keep up the continual supplies of "Remounts," necessitated by the wastage of warfare, the officer concerned will naturally find it impossible to put the time and minutiae in the examination of each individual animal, that would be possible were he examining a few race-horses (say) costing a small fortune a-piece. Yet with the method to be described, it will be found that with ordinary care, no unsound or radically unsuitable animal need be found among his final selection.

It is a good plan to have a number of the horses trotted round in a circle, the examiner standing meanwhile in the centre. It is then comparatively easy to divide the candidates for campaigning hardships into two classes: (a) The obviously unfit, either in size, action, conformation, or vice, and (b) Those animals which are more or less of the desired type. These latter are then examined for age and soundness in the ordinary way, and if satisfactory, and if they meet with the approval of the purchasing officer, they are branded on the hoof as a sign that they are purchased, and in order to prevent the possibility of substitution.

Having thus cursorily glanced at the duties and methods of the purchasing veterinarian, let us turn to the still heavier responsibilities of the man in veterinary charge of a horse-transport. Having been detailed to a boat, a wise precaution is to make as thorough an examination as may be practicable of the scene of one's future labours, with a view of having any alterations in structure or arrangements made which may be deemed advisable; for little things which count for inconven-

ience or worse at sea, can often be rectified in port at a trifling expenditure of time or money, though, if neglected, they might make a great difference to the success of the voyage.

An examination of the temporary surgery, which has probably been rigged up somewhere "aft," will reveal a woeful deficiency in one's favourite specifics, and this should by no means be overlooked, for few things are more worrying than to have a case out at sea, see it go from bad to worse, and be all the time reflecting—"If only I had so-and-so."

And now comes a still more important matter: one may with more or less complacency "throw physic to the dogs," according to idiosyncrasy, but no one will deny the all-importance of diet.

It would be beyond the scope of this article to enter into a dissertation as to the various food values of the different food-stuffs, as providing the fodder will not be within the veterinarian's province; but it will naturally be his first care to assure himself as thoroughly as may be that all fodder on board is sound, clean and dry, before sailing.

It is obviously futile to hurl anathema at a careless contractor's head, when one's charges are in mid-ocean. In this connection it may be noteworthy that sometimes hay may become damp before, or while being shipped, and is thus liable to become mouldy, and when this is the case one may expect digestive troubles. Here, again, "prevention is better than cure"; and a little forethought and trouble in port may save many an anxious hour at sea.

It is the general experience of shippers, I think, that horses do better at sea on a light diet for the first few days, until they "get their sea-legs." The diet should then be increased gradually, the amount *per diem* naturally varying with the size of the animal, the fact being borne in mind that when more food is introduced into the stomach than can be readily digested the action of the gastric fluids is retarded, and chemical changes, which lead to fermentation may possibly result. On the other hand insufficiency of food (which may easily happen from carelessness in giving one horse too much and his neighbour too little) will naturally tend to produce debility in individuals and a corresponding predisposition to contract any epidemic which may be latent, and which would be obviously difficult to deal with at sea, if only on account of the difficulty of isolation.

A word in conclusion as to the staff. The practitioner may possibly have an Army Veterinary Corps man or two on board to assist, if so, he will find them—if his experience be that of the writer—"a very present help in time of trouble." If not, he must, of course, do his best with the material to hand, which may vary from the conscientious, reliable hard worker, to the shirking scoundrel "out" to do as little as possible, and who probably has a tendency to smoke in prohibited hours, anywhere he can hide in, including the fodder holds, with a complete indifference to the safety of the ship, even though his own worthless carcass be part of the cargo.

In this connection, "example is better than precept," and any slackness tends to extend downwards, but in extreme cases, a few hours spent hand-cuffed to the ship's rail have a chastening effect, and cause the *mauvais sujet* to see the error of his ways. But such forcible measures should only be resorted to in extreme cases, and then only with the consent of the captain of the ship; for the willingness and thoroughness of work, so necessary for the success of the voyage, can rarely be obtained by coercion.

CHARLES C. ABRAM, M.R.C.V.S.

### Acidosis and Surgical Shock.

Last week we reprinted from the current number of *The Lancet* a note on observations on the causes of surgical shock. In the issue of June 1 there appeared a report of an investigation by Col. Sir ALMROTH E. WRIGHT, C.B., and Capt. LEONARD COLEBROOK, R.A.M.C., "On the acidosis of shock and suspended circulation." Apart from the direct application of the facts and principles involved, the subject, which has presented problems to the human practitioner for more than twenty years, has, to the man who does his own thinking, an attraction of its own, and the linking up with acidosis—a condition that was un-named and unknown a comparatively few years ago, lends additional interest. Acidosis was early recognised in the final stage of diabetes, and as a sequel to some conditions of malnutrition in young children: there it appeared to have a bio-chemical origin. Here it appears in different conditions.

The following excerpts are from the article of June 1st:—

"The suggestion that acid intoxication is an element in surgical shock we owe to Crile. For the establishment of the fact we are indebted to Cannon. His observations have shown that we have in the wounded man affected by shock a man suffering from a severe, sometimes an extreme acidosis. This discovery has therapeutic value; and it is of utility also as directing attention to a fundamentally important element in our vital machinery which has up to now been only imperfectly explored, and which medicine has, one may say, completely left out of account. I refer to the large output of acid waste products from the body, and the provisions by which, despite that, the alkalinity of the blood is maintained.

In connexion with the wounded man—To which of all the pathological agents brought to bear on him is his acidosis due? Whence have come the waste products which have produced that acidosis? What factors have influenced their convection into the blood stream? And how soon after it reaches the circulation is the acid disposed of? These problems considered, the question will come up as to whether the type of acidosis encountered in the wounded is not encountered also in other morbid conditions.

The outstanding feature in the symptomatology of shock being the fall of arterial tension—and interference with the circulation at the periphery—we may inquire first into the effect of arresting and reopening that circulation. We anaesthetised rabbits with ether, clamped one or the several main arteries, and removed the clamps after varying intervals—taking from time to time samples of blood for the measurement of the alkality. (Table).

In these experiments, when an artery is clamped and afterwards unclamped a very appreciable quantity of a non-expirable acid is conveyed into the blood stream. The same effect will, of course, be obtained with a ligature, tourniquet, or Esmarch bandage. It will be obtained, also, whenever the arterial pressure sinks away and afterwards recovers. For when we have collapse of the circulation, the blood stream is cut off from the periphery and metabolic exchanges are arrested; and when the blood pressure is restored capillary blood vessels are reopened and the metabolic exchanges fallen in arrears are resumed.

Our next series of experiments has reference to the effect of cold immersion. (Table).

There is a broad similarity between these results and those set out in the previous Table. There are, however, differences. In the first place, the acidæmia is here

much greater. *Secondly*—no doubt in correlation with the fact that the circulation in the limbs is not immediately arrested by the cold immersion—the acidæmia is already manifest when the animal is removed from the ice-bath. And, *thirdly*, when we here test the muscle (we do this by placing a piece of washed extirpated muscle on red and blue litmus paper) we find it definitely acid instead of alkaline as normal muscle, or amphoteric as muscle extirpated after simple occlusion of the artery.

*Resuscitation acidosis.* We see that bringing back the circulation increases the acidæmia, and that the blood returning from the muscles is more acidised than the blood taken from the right heart or vena portæ. And concurrent examination of the muscle reveals that, as the acidosis of the blood increases, that of the muscle decreases until its normal alkaline reaction is restored. A further point of practical import, brought out in connexion with rabbits 1 and 5, is that the animals, when they have to all appearance got over the effects of their cold immersion, may still be definitely acidæmic. It is shown that this acidæmia disappears after a few hours. This reversion to the normal may be safely assumed to be due to the acid being burned off in the system.

*Acidosis from hæmorrhage.* This question has already been settled in the affirmative by the experiments of Milroy, and we can see in two ways hæmorrhage must favour the development of acidæmia. It carries off sodium and potassium carbonates—the alkali available for the neutralisation of acid. And it depresses the arterial tension, and so interrupts the circulation at the periphery. That increases acid production in the muscles.

*Acidosis from violent muscular contractions.* We may now pass on to study the effect of increasing the metabolism of the muscles to the point at which the oxygen supply becomes inadequate. We can do this by powerful faradisation.

We have here, again, an acidæmia (Table). We see from the conditions of the experiment that it is a myogenous acidæmia; and we have confirmation of this in the circumstance that muscle tested immediately after tetanisation is, like muscle immediately after cold immersion, definitely acid. And there is also another point of resemblance between the acidæmia of tetanisation and that of arterial occlusion and cold. When it has not been carried too far the acidæmia passes off after a few hours.

*Acidosis of the wounded man.* As to the nature and genesis of the acid conveyed into the blood we may, as it seems to us, in the light of Fletcher's work on the metabolism of muscle in the presence of oxygen and in its absence, with probability conclude that both in our experiments and in shock as seen in the wounded man we are dealing with an acidæmia produced by lactic acid evolved in muscles which are by reason of arrest or collapse of the circulation cut off from their oxygen supply. When we think the matter over we see that this would be an acidæmia similar in character and derivation to that which develops in the dead body. The importance of recognising the fundamental identity of the acidæmia of shock and that which develops in the dead animal will presently emerge.

*Indications of Chilblains and Trench foot being associated with Acidosis.* It will be clear that the conditions which we dealt with in our ice-bath experiments and the conditions which produce chilblains and trench foot are essentially the same. From this we may safely argue that when acidosis is examined for in these conditions it will be found.

*Acidosis and Anæsthesia.* The pathology of trench foot and that of general anæsthesia would seem to lie poles apart. But in reality they would seem to have in common the factor of a shutting off of the circulation and a resultant cutting down of oxygen supply from the

muscles. This collapse of the circulation will, of course, be specially liable to supervene in severe and prolonged operations, in particular when undertaken in cold operating theatres. In animals—inasmuch as with them struggling, asphyxia, and terror, are inevitable accompaniments of every administration of anæsthetics—we are already as soon as the animal is under the influence of the anæsthetic confronted by a fully developed acidosis, and this will, if the animal remains in good condition during the anæsthesia, subsequently diminish. Cannon has emphasised the important practical points—the risk of superinducing upon the top of a 'wound-shock acidosis' an 'anæsthesia acidosis'; and the special risk of superinducing asphyxia when administering an anæsthetic to an already acidosed patient."

*Derivation of the Acidosis of Gas Gangrene.* Two years ago one of us pointed out that gas gangrene is characterised by the development of an extreme acidosis; and that gas-gangrene patients who are in a state of collapse and quite inoperable can be resuscitated and brought into a condition to stand operation by the intravenous administration of bicarbonate of soda. The utility of this procedure appears now to be established, and the treatment is widely resorted to. There remains, however, the problem of the source of acidæmia. In connexion with this it was at the time suggested that the acid was elaborated by the bacillus of Welch.

Now, in the light of the facts elicited by Cannon and ourselves, it has emerged that we must, in addition to acid elaborated by the microbe, take into our reckoning acid elaborated by muscle. That acid, converting as it would the alkaline muscle lymph into non-alkaline medium—i.e., a medium congenial to the bacillus of Welch—would provide for the infection a favourable point of departure. In connexion with this one of us has demonstrated that the fulminating gas-gangrene infection which is obtained in the dead animal is due to acid conveyed into the blood after death; and, further, that a quite similar rapid pullulation of the microbe takes place in blood drawn off from the dead animal after the post-mortem acidæmia has developed. The results set out (Table) are those of typical experiments.

There is another way in which acid produced in muscle may intervene in gas gangrene—not at the outset of the infection, but at the height of the toxæmia. In that toxæmia we have invariably a collapse of the circulation comparable to that obtained in cold immersion; and to this might not unreasonably be ascribed, at any rate, the rapid progress of the acidæmia.

*Resuscitation procedures in Shock.* The ideas which we have been developing have clearly a direct bearing on the policy to be adopted in the treatment of cases of shock—the warming up of the patient, and the intravenous injection of alkali recommended by Cannon. But there is an important distinction to be established. As a prophylactic measure the giving of hot drinks and the application of warmth is assuredly the ideal procedure. For by maintaining the circulation the acidosis will be prevented. No such enthusiastic view can be taken of heat applied as a remedial procedure in fully developed shock. Inevitably it will convey into the blood stream additional acid, increasing the acidæmia. Our experiments upon rabbits subjected to cold immersion have very vividly impressed upon us that too rapid resuscitation by warmth—i.e., a too precipitate washing of muscle acid into the blood—may be perilous to life. We venture to suggest that this possibility should, in connexion with resuscitation procedures—and not only in those applied to the wounded—be constantly kept in view. And it would seem to us theoretically desirable, for the avoidance of resuscitation acidæmias, wherever possible, to commence procedures by a bicarbonate of soda injection.

## THE U.S.A. ARMY VETERINARY SERVICE.

By the Act of Congress approved June 3, 1916, the Veterinary Corps was placed in the Medical Department of the United States Army. Up to the time of the present war this service was not organised and no enlisted personnel was authorised. Under Act of Congress approved May 18, 1917, a special order was issued by the Secretary for War authorising the organisation, for the period of the existing emergency, of a Veterinary Corps, National Army, which should consist of 1 commissioned officer and 16 enlisted men for each 400 animals in service. The proportion of animals to men in war is about 1 to 4. One good horse or mule is capable of doing practically as much work as four men. Animals are afflicted with many diseases that are common to man and some of them communicable to man. Statistics show that about 10 % of the animals in the army are constantly incapacitated. In former times this percentage has been much higher and the unfit animals were carried along with those that were working. This plan necessarily interfered with the mobility of an army. Much better results have been obtained by sending unfit animals back of the lines for treatment, where supplies and trained assistance are provided. Under the old plan it was possible to cure only about 60 % of those incapacitated, while under the more modern methods practically 90 % are cured and become more useful than green horses that are purchased for the army service.

The Veterinary Service in the United States Army is comparatively a new organisation. In our civil war most of this work was done by the chief farrier or the chief blacksmith. In March, 1863, Congress passed an Act abolishing these positions and provided one veterinary surgeon for each regiment of cavalry. President Lincoln evidently appreciated the value of veterinary service to the army. He offered to some of the best veterinarians in the civil war the subaltern rank of lieutenant. They believed that they should have the rank of captain and unfortunately declined the rank offered. It is believed now that they should have accepted the rank, demonstrated their ability and made their service a necessity.

In later years veterinary schools were organised and decided progress has been made in preventing and treating the diseases of animals. At the present time there are a number of state schools all of which require a preliminary education of at least four years high school and a professional course of four years. These schools are now turning out men who are well trained in the diseases of animals, animal hygiene, and meat and milk inspection. With necessary organisation and direction it should be possible to utilise these men in building up a veterinary service for the army that will be a credit to the Government. It is unfortunate that the work of organising this service could not have been completed in times of peace. Under present conditions it has required a great deal of extra effort on the part of the War Department and the Surgeon General to provide for the service.

Up to the time of the present war the veterinary service was unorganised. There was no system of keeping records or directing the service. Fortunately, there were among the few men in the regular veterinary service of the army some who had served long and faithfully in the army and had kept informed of the progress made in veterinary medicine in general, and especially in that part which pertained to Army Veterinary Service. The Surgeon General ordered three of these men together with a few veterinarians from civil life to come to Washington to assist in organising the veterinary service. The following veterinarians have been assisting the Surgeon General in this work for the past three months: Major Gerald E. Griffin, Capt. Ray Stancliff,

Lieut. A. L. Mason, David S. White, dean of the Veterinary School, Ohio State University, L. A. Klein, dean of the Veterinary School, University of Pennsylvania, Charles E. Cotton, member of the Minnesota State Livestock Sanitary Board, and President of the American Veterinary Medical Association, and C. J. Marshall, State Veterinarian of Pennsylvania.

The plan of organisation outlined for the Veterinary Corps is practically the same as that of the Medical Corps. Provisions are made for advance and base veterinary hospitals, veterinary service in connection with the purchase and transportation of animals at posts, in camps, on the march, embarkation depots and on transports. The veterinary officer in charge of the administration of the Veterinary Corps is under the Surgeon General. Other veterinary officers in charge of corps, divisions, brigades, posts, detachments, regiments, etc., have the same relative titles as those of the Medical Corps and stand in the same relative position to the Surgeon General.

The work of organising the veterinary service is practically completed. It is hoped that good results will be obtained. The service will be useful to the army and animal husbandry in general, and will encourage schools to extend or maintain the high standards which some, but not all, have already adopted.—From *Journal of the American Veterinary Medical Association*.

## Dipping and prosecution for Scab.

In the Oban Justice of Peace Court, Charles Cargill, farmer, Pitarrow, Fordoun, Kincardineshire, was charged with having on or about 11th April last sent or conveyed, or caused to be sent or carried, by the Caledonian Railway Company, seven Blackface ewe hogs and six Blackface wedder hogs which were affected with or suspected of sheep scab, contrary to the Diseases of Animals Act, 1894, and the Sheep Scab Order, 1905. Mr. James Coats, J.P., Fiscal, appeared for the prosecution, and the respondent, Mr. Cargill, was represented by Mr. R. A. MacVicar, solicitor, Oban. A plea of not guilty was tendered.

Mr. MacVicar pointed out that his correspondent (Mr. Cargill's solicitor at Laurencekirk) took up the position that the question of whether the sheep mentioned were affected with scab or not was irrelevant in view of the fact that the respondent was authorised by the local authority to have the sheep removed, and that in so doing he had the authority of the Board of Agriculture's orders, and was thereby protected.

Mr. Coats replied that what he had to prove was the question of fact as to whether the sheep came from Laurencekirk and were found to be affected with scab on their arrival at Taynuilt. The fact that permission for removal was granted could not relieve the respondent of responsibility.

The Chairman, ex-provoost F. W. Cooper, held that the Court had only to deal with the complaint before them. They did not know anything about the local authority.

Constable Roderick Mackenzie said he saw Mr. MacDougall's sheep being untrucked at Taynuilt station on the evening of 12th April. There were 241 sheep in the lot, and he suspected from their movements that some of them were affected with scab. He thereupon examined one of the animals, and it was pretty bad. He examined five that evening, and found all of them affected. He sent some of the wool to Superintendent Mackenzie, Oban. On the following Monday (15th April) witness went to Drissaig farm and examined all the sheep which came back from the wintering at Laurencekirk. He found 13 had scab. All the animals affected looked as if they had had the disease for a considerable time previous to 15th April.

Peter MacNicol, shepherd at Drissaig, corroborated' and John MacDougall, veterinary surgeon, Oban, gave evidence as to his examination of wool sent him, and subsequently of the sheep at Drissaig, when he found 13 hogs suffering from sheep scab. The sheep in question could not have become affected with scab between 12th April, the date of their return from Laurencekirk, and Monday, 15th April, when he examined them.

In reply to Mr. MacVicar, witness said it was quite possible for the sheep to be affected with scab on 15th April, although they might have been double dipped at Laurencekirk on 20th March and 2nd April.

Charles Cargill, the respondent, stated in examination by Mr. MacVicar, that Mr. MacDougall's sheep arrived at his place for the wintering in October, 1917, and they were dipped about 10th November. Witness informed the local authority of his intention, and they sent an inspector to see the dipping carried out. At that time witness did not notice anything wrong with the sheep. About the end of December the Chief Constable of Kincardine received a notice from the Board of Agriculture intimating that Mr. MacDougall's sheep should be double dipped, as they had been in contact with sheep affected with scab. That dipping was carried out in December and January, Mr. MacDougall, the owner of the sheep, attending the second dipping. In the month of March witness suspected the sheep were again showing signs of scab, and he at once reported the matter to the local authority as well as to Mr. MacDougall. The sheep were dipped on the 20th March. A very strong dip was used. Seven of the animals seemed to be affected. These were hand-washed. On 2nd April the sheep were again examined by the local constable, the sheep formerly found infected being again hand-washed. The sheep at that time all appeared to be clean, and witness applied to the local authority for permission to have them removed. The bargain was that the sheep were to be returned on 1st April. As the representative of the local authority considered that the sheep were clean, witness received the necessary authority to return the sheep to Argyllshire.

Police Constable Wm. Napier, Auchanblae, Kincardineshire, the local inspector under the Diseases of Animals Act, gave evidence as to the various dippings carried out by the respondent.

Charles George, Chief Constable, Kincardineshire, who was the Chief Inspector for the local authority under the Diseases of Animals Act, said the first he heard of the sheep was about 20th December, when he was asked by the Board of Agriculture to see that the sheep in question were double dipped, as scab had broken out at Drissaig farm. That was done, the dipping took place on 22nd December and 3rd January. He reported the dipping to the Board of Agriculture, and asked the local inspector to keep an eye on the sheep. About 19th or 20th March the local inspector again reported that there were symptoms, and the sheep were again double dipped. On the 9th April witness received a telephone message asking if Mr. Cargill could send the sheep home to Drissaig. He replied in the affirmative, as the local inspector had reported that the sheep were free of the disease. He granted the necessary order. Witness was greatly surprised when he heard from Supt. Mackenzie, Oban, that scab had been discovered on the sheep when they returned from Kincardine.

In reply to Mr. Coats, witness said, in view of what had happened, it would have been wise to get a veterinary surgeon to examine the sheep, but he followed out the course recommended by the Board of Agriculture's inspector in the month of December.

The Chairman said that this was the most curious case of sheep scab prosecution that had ever come before him. It amounted to this: that all parties had observed the regulations, but the regulations were not sufficient

to carry into effect the purpose intended. As the object of these prosecutions was to stamp out sheep scab, he thought the attention of the Board of Agriculture should be drawn to this particular case, so that the Board might see that the regulations were sufficient for the purpose in view.

Mr. Coats pointed out that the offence consisted in removing sheep which were affected with scab. It did not matter how many double dippings the sheep got; what the Court had to deal with was that scab was discovered immediately on the arrival of the sheep at Taynult. It was the duty of Mr. Cargill, the respondent, to see that the sheep were clear of scab when they left his farm; but the curious thing was that from first to last no attempt had been made to call in a veterinary surgeon. The practice in Argyllshire in such a case was that sheep could not be removed without a certificate from a veterinary surgeon.

Mr. MacVicar said that in this case the respondent had followed the correct procedure. Mr. Coats seemed to imply that the onus was on Mr. Cargill to call in a veterinary surgeon to see whether there was scab or not. The respondent had conformed with the regulations of the Board of Agriculture, and he had therefore done everything he was asked to do.

The Chairman said he could not see how that statement could clear Mr. Cargill of the charge of removing sheep which were affected with, or suspected of, sheep scab.

The Court found the charge proved, and a fine of £2 2s. was imposed.

The Chairman, in announcing the decision, said the fine had been limited in this case for the reason that it appeared that Mr. Cargill had made quite a reasonable effort to comply with the regulations, as these were interpreted in Kincardine, but that interpretation did not seem to the Court to be sufficient to carry out the purpose in view, which was to prevent sheep affected with scab being carried by rail.

Mr. MacVicar asked the Court to state a case.

## ARMY VETERINARY SERVICE

War Office, July 26.

The King has been pleased to approve of the following Awards to the following Officers and Warrant Officers in recognition of their gallantry and devotion to duty in the Field:—

### THE MILITARY CROSS.

\* \* \* \*

Temp. Capt. J. S. YOUNG, A.V.C.—He took over a large number of horses, stampeded by shell fire and wounded; with great coolness and resource he restored order, and although the enemy were rapidly advancing he placed wounded men on the horses, and so assisted them to a place of safety. He also completed the arms and equipment of fighting troops from the packs of stray horses.

War Office, Aug. 6.

The names of the following have been brought to the notice of the Secretary of State for War by Lieut.-Gen. Sir J. L. van Deventer, K.C.B., Commanding-in-Chief, British Forces East Africa, for distinguished services during the operations from May 30 to December, 1917:—

### ARMY VETERINARY CORPS.

Capt. W. W. Henderson.

### SOUTH AFRICAN V. CORPS.

Capt. M. Cunningham, Capt. F. J. Dunning, Capt. A. M. Howie.

EAST AFRICAN V.C.—Capt. M. H. Reid.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Aug. 1.

## REGULAR FORCES. ARMY VETERINARY CORPS.

Temp. Capt. W. C. Quinell relinquishes the actg. rank of Maj. on ceasing to hold the appt. of Dep. Asst. Dir. of Vety. Servs. (July 16).

Capt. J. Harrison to be actg. Major while holding the appt. of Dept. Asst. Dir. of Vety. Servs. (July 16).

Temp. Lt. to be temp. Capt.:—R. B. Crichton (July 18).

To be temp. Lieut.:—E. K. Smith (July 15).

Temp. Qrmr. and Hon. Capt. T. F. Flood relinquishes his commn. and is granted the hon. rank of Capt. (Aug. 1).

Aug. 2.

Maj. W. C. Lowe, F.R.C.V.S., relinquishes the actg. rank of Lt.-Col. on ceasing to be specially empld. (May 5).

Maj. W. C. Lowe, F.R.C.V.S., to be actg. Lt.-Col. whilst empld. as Asst. Dir. of Vety. Servs. (June 18).

To be temp. Lt.:—R. G. Linton (July 15).

Aug. 3.

Temp. Lt. to be temp. Capt.:—C. F. Johnston (June 11).

Aug. 6.

Capt. to be Maj.:—P. V. Beatty (Nov. 2, 1916, sen. July 10, 1915, and prec. next below Maj. E. S. Gillett, C.I.E.). (substituted for notification in *Gazette* July 24).

Maj. A. E. Clarke, Res. of Off., to be actg. Lt.-Col. while holding the appt. of Asst. Dir. of Vety. Servs. (June 16).

To be temp. Lts.:—C. W. Elam (July 15); R. C. Scott (July 17).

Aug. 7.

Temp. Qrmr. and Hon. Lieut. to be Hon. Capt.:—H. R. Rose (June 1).

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

R. H. Bird, Greeley, Colorado	£1	1	0
F. T. Harvey, St. Columb, Cornwall	1	1	0
W. A. Macgregor, Capt. A.V.C. (T.F.)	1	1	0
A. V. Nicholas, Capt. A.V.C.	1	1	0
J. Richardson, Capt. A.V.C.	1	1	1

Previously acknowledged 935 2 11

£940 7 11

## OBITUARY.

LAWTON S. SEDGWICK, M.D., M.R.C.V.S., Rangoon.  
Graduated, Glas: May, 1904.

Mr. Sedgwick died at Bwlcheroesfaen, Iaygarreg, R.D., Montgomery, on 25th July, aged 42 years.

H. THACKERAY, M.R.C.V.S., Eastgate, Stafford.  
Lond: July, 1900.

The death of Mr. Harry Thackeray, partner in the firm of Carless and Thackeray, veterinary surgeons, of Stafford, took place at his residence, Wolverhampton Road, on Sunday, July 28. The deceased gentleman was the son of a cotton-spinner at Stalybridge, his father dying when Mr. Thackeray was a boy. He came to Stafford and was articled to Messrs. Ginders and Turnor, estate agents, but later took to the study of

veterinary practice, and passed his examinations with high honours. He started in practice at Eccleshall, but afterwards joined in partnership with the late Mr. Wm. Carless, on whose death Mr. Reginald Carless joined the firm. The deceased gentleman, who was 51 years of age, had been in poor health for some time. As a young man he was a member of the Stafford Athletic Club. His wife died about three years ago. There are two children. The funeral, preceded by a Mass at St. Austin's Roman Catholic Church, took place at the Cemetery on Wednesday.

## DISSATISFIED.

To the Editor of "*The Veterinary Record*."

Dear Sir,—In your editorial article dated July 27th, you draw attention to certain privileges granted to the profession. You remark that, "much of this is due to the vigilance and ability with which the chief representatives of the Council have furthered our just claims." May I be permitted to trespass on your valuable space to suggest that perhaps there are many of the profession who are of opinion that the work of the Council is not what it might be?

The advantages which your article mentions, namely, concessions as regards petrol, rations, etc., are certainly of value—but only to those members who are carrying on practices at home. We hear of their increased work and the extra demand made upon them, but surely they are getting paid for it, and veterinary surgeons at home are experiencing a time of prosperity.

Now as I believe the majority of the profession, and certainly all of what I term the younger members, are serving with the A.V.C., may I ask, What have the Council done for them? You say that we have been treated "no better or no worse than it (War Office) is accustomed to treat other professional men." I think that is hardly correct. A doctor joining the R.A.M.C. can receive consolidated pay at 24/- per day—an increase of about 5/6 per day of a V.S. Junior officers of most branches of the Service have, since war started, been granted two increases of pay. Under conscription I see no reason why a professional man should receive higher pay than that of a combatant officer, but it is hard on those who gave their professional services at the commencement of the war, having based their calculations of their being able to keep their families, premises, etc., on their pay at the then value of the sovereign. Now, though the value of money has decreased yet no attempt has been made to compensate these men, as in other branches of the Service. A 2nd Lieut. now receives 10/6 per day instead of about 5/11 at the commencement of the war. The A.V.C. officer receives the same as when the war started.

Furthermore, have the Council taken any interest in the condition of affairs of officers of the A.V.C.—whether satisfaction is given as to methods adopted in promotion, honours, etc.? I believe I am expressing the dissatisfaction that is among many junior members of the profession.

I regret having to use a *nom de plume*.—Yours faithfully,

August 8th.

"ONE OF MANY."

## A way with Fraudulent Remedies in U.S.A.

Seizures of sixty-two cases of a so-called hog-cholera remedy in Iowa and North Carolina upon order of the Federal Courts mark a determined effort on the part of the United States Department of Agriculture to stop interstate traffic in so-called hog-cholera remedies which do not cure, prevent nor control this disease which has such an important bearing on the Nation's pork supply. The seized goods are now in custody of United States Marshals pending action under the Food and Drugs Act. The Government charges that this remedy will not prevent or cure hog-cholera, as claimed on the labels of the seized products.

The Bureau of Animal Industry, through its veterinarians and experts in animal diseases, is cooperating actively with the Bureau of Chemistry in this campaign to control interstate traffic in fraudulent stock remedies.

#### Notes on the Isle of Wight Bee Disease.

Bee disease does not appear in the professional curriculum of the veterinary surgeon, and therefore the following note—one of several which have appeared in *The Pharmaceutical Journal*—is unlikely to appeal directly to more than a very few of our readers. One question that suggests itself is, Who should attend to it? It scarcely seems to belong to the rôle of the medical man; or to the prescribing chemist. And it may be remembered that one of the early achievements of Pasteur was a successful investigation of silkworm disease, which was the means of preserving a great national industry. There is not so much to be said for the conservation of the honey crop: but we are reminded by several obtrusive and unmistakable conditions of life that we are living on islands; and it is not a long jump to the idea that if we want to go on living—in reasonable comfort—we must conserve all sources of food, both now and in the future.

Without entering into a comparison of the relative merits of the two "schools of thought," Aberdeen and Cambridge, as to the contributory causes of bee disease, a brief report as to the present position of the epidemic will be of interest. Taking the case of one apiary of forty-six hives, all of them imported last year from the mainland, and which seemed in perfectly good health at the end of the summer, it was found on examining the broods last week that twenty-eight out of forty-six had perished. Whether the remainder will survive the rest of the winter it is difficult to say. This proves to a certain extent that feeding with medicated sugar is a failure.

Following Mr. Anderson's line of thought that sugar feeding is detrimental, a case in point is as follows:—A brood of bees escaped from a hive over three years ago, and took up their habitat in the roof of a barn. In a

state of nature be it said, they have survived three winters of severe weather, and, as far as I know, are still going strong. However, the sugar theory breaks down when we take into consideration that a disease arising from sugar feeding would have been widespread, instead of being localised, as it was at the first, seeing that sugar feeding is general all over Great Britain.

Going back to the time of the outbreak of the disease in a virulent form, some fourteen years ago, the island was swept from end to end, and practically every hive of bees perished. At that time a comb of honey taken from a hive in which the disease was prevalent was brought to me for examination, and the least that could be said about it was that it was one mass of filth. The theory that the disease is not spread by coming in contact with the excrement of those affected, seeing that bees, as a rule, evacuate some distance from the hive, does not hold good. If one bee in the hive becomes affected it becomes so weak, and the dysentery so acute, that the insect is unable to leave the hive, with the result that the excrement is dispersed wherever it may happen to crawl. Sometimes it happens that bees come outside the hive and are unable to return, and finally die from exposure. It is obvious that the immediate neighbourhood of the hive must be contaminated. Mr. McLanachan's ideas of drastic disinfection are perfectly justified, and, from many points of view, if bee disease is not infectious, it looks remarkably like it.

D. F. RITCHIE.

Newport, Isle of Wight.

#### Sheep Diseases investigation.

At a meeting of the directors of the Scottish Chamber of Agriculture held on Friday, 26th July, a letter was read from Mr. Hugh Duncan, LL.B., secretary of the Glasgow Veterinary College, asking the co-operation of the Chamber in raising funds for the investigation into diseases of sheep breeding to be carried out by Professor Gaiger. Reference was made to another investigation along the same lines already in progress, and the secretary was instructed to obtain information regarding the relation between the two.

## HORSES AND MOTORS.

Amongst the many problems of the near future, one which will affect the veterinary profession both in practice and in pocket, will be the relative position of horses and motors in traction and transport. Anything like the huge displacement of horses which took place in the large towns with the advent of electrical traction is, of course, impossible, but for some years there has been a steady increase in the development of heavy motor transport with relative displacement of heavy and middle weight draught horses. The present shortage of petrol is owing chiefly to two causes—the demands of military service with its thousands of motor lorries and other vehicles; and the deficiency of freightage, from like necessity. These causes are both temporary; and with the added experience of what can be done with motor power on heavy vehicles it is more than probable that there will be an increased use of them in civil occupations.

In the direction of agricultural work there is at the moment a great increase in motor traction; there are thousands of engines in use attached to implements which were formerly horse-drawn. Many of these may be said to be on trial; a few have "come to stay", foremost among them Wyles motor plough, Fowler's, of Leeds, with others of similar type. The acceleration in the work of the plough in the farmer's everlasting gamble against time and weather makes that a foregone conclusion. The heavier types of general utility engines are on a different footing: the heavy-land farmer "has no use for them"; the light-land farmer can do with a less powerful engine. The life of the lighter built engines will be relatively shorter—and in all there is the question of time lost in stoppages, and of cost in repairs. So that although there is probability of a reduction in farm horses, it is yet a long way to the disappearance of the horse from agricultural work. This, and the increased value of live stock—now and for some years to come, which has resulted in the stock-owner finding that it pays him to utilize the knowledge and skill of the veterinary surgeon, will go far to maintain the country practitioner. To help in this direction other animal diseases are gradually being brought under control. And there is room for extension: our agricultural practice has not yet touched the poultry yard—on the continent and in U.S.A. this has been in the hands of the veterinarian for years.

So far, then, as the present outlook carries us, it appears that the future for the country practitioner is distinctly hopeful, while that of the townsman as affected by horse practice, is decidedly less so.

## AN INTRA-PALPEBRAL DIAGNOSTIC REACTION FOR EPIZOOTIC LYMPHANGITIS.

Lanfranchi published an article upon this subject in *Il Moderno Zoofatro* for 1917. The diagnosis of epizootic lymphangitis does not generally present great difficulties. The clinical picture, in its typical demonstration, is characteristic; and the microscopical examination of closed or recently opened nodules shows the cryptococcus of Rivolta. Sometimes, however, on account of the diverse phases of the evolution of the disease, the variations which that evolution may present, or the diversity of its localisations, a clinical diagnosis is not possible. Lanfranchi has, therefore, attempted to discover a specific diagnostic reaction.

As inoculating material he has used pus aseptically obtained from mature but still unopened nodules, and very rich in cryptococci. His preparatory technique is as follows. He adds two parts of sulphuric ether to one part of the material, shakes the mixture frequently, and leaves it for twenty-four hours. He then evaporates the ether by means of a water-bath, restores the material to its primitive volume by adding distilled water, shakes it afresh, and leaves it for another twenty-four hours, after which he places it in a water-bath at 80° C. for from 15 to 20 minutes. When it has cooled, he places it in an electric centrifuge at from 2000 to 3000 revolutions per minute for from 20 to 30 minutes, after which he decants the liquid part, which is that to be injected. The dose varies from 2½ c.c. to 3 c.c., according to the richness in cryptococci of the pus used; and the injection is made intrapalpebrally as in the case of mallein.

In healthy horses, in glandered ones, and in those suffering from strangles or ordinary lymphangitis, the injection of the extract obtained in this manner produces an oedema limited to the point of injection, or at most to the lower eyelid. The oedema commences at the end of one or two hours, reaches its maximum at the end of eight or ten hours, and disappears totally in from 20 to 24 hours.

In horses affected with epizootic lymphangitis the local reaction commences at the second hour, and in the fourth hour is diffused all over the lower eyelid, notably diminishing the palpebral fissure. The oedema augments, and in from twenty-four to forty-eight hours reaches the inferior limit of the zygomatic crest. This reaction persists for some hours, and disappears gradually. The oedematous part is tense, warm, and very sensitive.

In addition, purulent conjunctivitis is observed. At the end of four hours, small clots of a yellowish material are seen in the internal angle of the eye,

and these increase in the next twenty-four to forty-eight hours. In some animals the discharge is abundant, and flows out from the lower eyelid.

These manifestations are more intense and more lasting in animals presenting incipient lesions, the nodules of which are not yet mature and are few in number.

The local positive reaction is accompanied by a certain thermic reaction, which commences seven or eight hours after the injection, reaches its maximum at from the eighteenth to the twenty-fourth hour, and returns to the normal at the end of from twenty-four to forty-eight hours. A general reaction, on the contrary, is absent in the majority of cases.

Lanfranchi concludes by admitting that his experiments do not yet confer a general practical utility upon the method. That can only be gained when a culture medium is found in which *Rivolta's cryptococcus* develops luxuriantly and abundantly. —(*Revista de Veterinaria de Espana*).

#### PULMONARY SARCOMA CAUSING SYMPTOMS OF EMPHYSEMA.

Fröhner recorded this case in the *Monatsheft für praktische Tierheilkunde*. An eight-year-old mare showed symptoms of intense pulmonary emphysema—great dyspnea of marked abdominal type, respiratory movements numbering from 60 to 80 per minute, excessive extension of the tympanic sound upon percussion as far as the last rib, absence of pulmonary sonority in the pulmonary zones, and accentuated vesicular respiration. Post-mortem examination revealed sarcoma of both lungs. The lungs were double their normal volume, and section revealed numerous hard sarcomatous centres ranging from the size of peas to that of beans. The case shows that it is not possible to diagnose pulmonary emphysema with absolute certainty during life.—(*Revista Veterinaria de Espana*).

W. R. C.

#### PERSONAL INFLUENCE OF THE INSPECTOR.

By Dr. W. H. DALRYMPLE, Department of Veterinary Science, Louisiana State University, Baton Rouge, La.

The following is an abstract of a highly instructive address delivered by Dr. Dalrymple at the conference of Bureau inspectors engaged in tick eradication work held at New Orleans, Louisiana, January 15-18, 1918.

[We reprint this abstract with not a little pleasure: First because Dr. Dalrymple is an old correspondent—he is a Glasgow College graduate—and we are pleased to see him "making good." Secondly because he is here urging a point that has several times been put forward in these pages—that it is necessary, very necessary, to attend to the education of the stock owner. It is true that we have not tick-fever nor, at present, pleuro-pneumonia to deal with: but there are others to "get on with."]

"THE MAN IN AUTHORITY. One of the most desirable and valuable qualifications in the man with authority is first of all an accurate knowledge of the work over which he presides and the gift of being able to handle other men satisfactorily. Although a man may be a master in the details of his work, yet if he is lacking in

the personality and tact necessary to success his manner is more liable to repel than attract people to him, with the resultant lack of cooperation afforded him, and consequent hindrance to the accomplishment of the ends desired.

It is generally conceded that the greatest obstacle to the most successful prosecution of veterinary sanitary work, in which may be included tick eradication, is the gross ignorance of the people as to the procedure and the ultimate result sought. Antagonism is displayed despite the fact that the work is carried on for their individual benefit and that of the community and state in which they live. And yet, without some effort being consistently and continuously exerted to dispel such ignorance, final success must of necessity be considerably delayed. Hence in this particular phase of the work success depends largely upon the men in authority being endowed with personal magnetism and tactfulness.

(Dr. Dalrymple at this point related several entertaining instances in his early work as a veterinary inspector in Ireland in connection with contagious pleuro-pneumonia. The reminiscences illustrated very forcibly the value and importance of tolerance and tactfulness in inspiring confidence in the people, and securing their good-will and cooperation).

OBSTACLES TO TICK ERADICATION. Anyone who has been in touch with tick eradication since the beginning of the campaign knows the trials and tribulations through which he has had to pass and the many obstacles which have incessantly confronted him. While many of these have been overcome there still exist, and will to the end, those of a similar character which must be tackled.

In mentioning a few of these obstacles I think we may give ignorance, which might be extended to gross all-round ignorance on the part of the laity, the very first place. Ignorance concerning the true object to be attained; ignorance regarding the fever tick and its life habits; ignorance concerning the methods of procedure for the destruction of the parasite and the fever with it; and ignorance as to the value of the work to the individual cattle owner, etc.

It appears to me, that with an average amount of tact, and a little more condescension, if you will, a great deal of this ignorance might be dispelled by a little man-to-man and heart-to-heart talk concerning the various phases of the problem. In other words, letting in the true light to the darkened understandings, for the normal individual, even with the densest sort of comprehension, may be made to see and understand if only the problem is clearly explained to him and more particularly if it is done in a tactful way and in a manner which appeals to the man, arouses his interest, and gains his confidence, friendship, and good-will.

True, suspicion is a dominant factor with many of these people. This, too, is born of ignorance, through erroneous information proffered by similarly ignorant or suspicious individuals. Once ignorance is dispelled, suspicion also will gradually vanish.

The lack of cooperation is a tremendous obstacle in this important work; and where are we to place the cause for this want of sympathy, if not in the ignorance of so many of our people? Cooperation suggests correct understanding and enthusiasm; and once the people get understanding through enlightenment, cooperation is bound to follow. It cannot be otherwise; a man may be ignorant, but that is no indication of his being a fool, to his own detriment, if once he sees the light.

SELFISH OBJECTORS. There is another class of people who, although they may not be wholly ignorant of conditions, yet for selfish personal reasons frequently obstruct the progress of tick eradication. I refer to the man with cattle but with insufficient or no pasture of his own, and depending for the sustenance of his cattle

upon free range or the generosity of his neighbour. This man fears a stock law which he considers would interfere with his business, and for purely personal reasons he has no sympathy with the work, and blatantly calls out for "personal liberty," which he seems to interpret as the right to selfishly benefit himself at the expense of his neighbour and everybody around him. Then we have the unpatriotic citizen who seems to object to contribute his due share to taxation through legitimate assessment of his cattle, which he believes the work of tick eradication would force him to do. We are all familiar with these obstructionists, and time will, of course, eventually straighten them out through the general enactment and enforcement of suitable legislation. This desirable result, however, may be very materially assisted by accurate information judiciously and tactfully imparted to the people themselves.

There is another class of obstructionist who bobs up periodically and who, unfortunately, is rather effective in his methods. I refer to the little politician with some petty political office in view. This man carefully feels the pulse of his community regarding the tick eradication question, and if he finds that ignorance prevails and consequently an aversion to the work, he loses no opportunity to add to this ignorance and to strengthen the people in their spirit of aversion. He simply plays upon the credulity of the uninformed, so that he may successfully ride into office through their votes.

This class of citizen usually knows better, but his campaign is conducted in an absolutely selfish manner, without any regard whatever for the real good of his neighbours or for the successful development of his community or of his state. He is a dangerous man, however, because through his sophomoric campaign talks and speeches he is frequently able to sway the minds of the people, and in some instances the minds of the local authorities in the county, whose assistance and cooperation are so much needed to successfully carry on the work, by posing as the "friend of the poor farmer" against imaginary governmental aggression.

Even in a case of this kind there is a remedy. The "toxin" of ignorance must be carefully combated by the judicious use of the "antitoxin" of knowledge. In other words our poorly informed people must be educated, so that they may be able to think intelligently for themselves and base their conclusions upon proved facts.

**SUMMARY.** As this whole matter appears to me, it would seem to resolve itself into two main issues, *viz.*:

1. The fact that great ignorance still prevails concerning the work of tick eradication, and which must of necessity be dispelled before we may hope to reach the goal of tick freedom in the shortest possible time; and

2. That the only feasible method to accomplish this, as I see it, is through the education of the people; which I believe will largely devolve upon the county inspector, who is presumed to come into daily contact with the cattle owners in his immediate locality.

This would suggest, therefore, that the inspector must not only be familiar with every phase of the work, but he should be an educator—shall I say of the kindergarten type? because it should be remembered that his "pupils" are but babies in knowledge of the problem he is trying to solve. He should be patient, tolerant, and sympathetic, but withal he should be firm, and he should be a student of human nature, so that he may draw the people to him through being able to adapt himself to their various idiosyncracies, their peculiarities of temperament, etc.

Education, therefore, is the surest weapon we possess with which to bring the tick fight to a "peaceful issue" in the shortest time possible, because it will bring with it all other measures necessary to accomplish the final result.

I fully realize, of course, the magnificent work that has already been done in the face of all the obstacles mentioned, and no doubt others which I have failed to allude to. There is a great deal yet to be accomplished, and there is still an immense amount of gross ignorance, and what I have said is more in the nature of an appeal to those who expect to be in the fight during the remainder of the campaign.

Finally, we must always bear in mind that this country is at grips with the most powerful (military) and relentless foe which possibly the world has ever known, in the greatest conflict of which there is any record in history, and on the outcome of which depend momentous consequences. Therefore, everything that it is possible to do to conserve and increase the food supply in meat and meat-food products at this time of stress, and for some time in the future, should be done, not alone from the standpoint of patriotism but as an absolute necessity—in fact a war measure. I am of the opinion that the successful early completion of the work of tick eradication in the South will be one of the most potent factors in aiding our country and our associates in the war to decide the conflict favourably."—*Journal of the American Veterinary Medical Association.*

#### ROYAL COUNTIES VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A.—SOUTHERN BRANCH.]

A meeting was held at 50 Friar Street, Reading, on Friday, July 26, when Mr. J. Willett, President, was in the chair; and there were also present: Messrs. F. W. Willett, Staines; J. Parker, Faringdon; J. R. Baxter, Lechlade; and G. P. Male, Hon. Sec. and Treasurer, Reading.

Apologies for non-attendance were received from Messrs. W. A. Hancock, Uxbridge; J. East, Aylesbury; S. H. Slocock, Hounslow; T. B. Goodall, Christchurch; W. Pauer, Blackwater; G. E. King, Abingdon; J. Varney, Winslow; J. McKerlie, Hungerford; R. J. Verney, Oxford; J. W. McIntosh and Prof. G. H. Wooldridge, London.

**Correspondence.** In January the Association passed a resolution expressing sympathy with Mr. King in his illness, and Mrs. King had written acknowledging the letter with many thanks.

Mr. Bullock had also written acknowledging a special donation of £1 19s. 4d. to the Victoria Veterinary Benevolent Fund, and expressing the hope that the excellent example set by the Royal Counties would be followed by other Societies.

**Election of Members.** The following were elected members of the Association: Prof. G. H. Wooldridge, F.R.C.V.S., London; Mr. F. W. Willett, M.R.C.V.S., Staines; Mr. R. G. Gillard, M.R.C.V.S., Oxford.

The Hon. Sec. said that since their last meeting Mrs. Willett, wife of their esteemed President, had passed away. He was sure they would wish to pass a vote of condolence to him in his very great bereavement. Mrs. Willett was a personal friend, and also a very great friend of that Association. He attended the funeral as representing the Association.

The vote was passed in silence, all the members standing.

The President made feeling acknowledgment.

#### VETERINARY FEES.

The meeting then discussed a resolution passed by the National V.M.A. at their last meeting in London, re an increase in Veterinary Fees.

The President said that their Secretary and he attended that meeting in London, and it was chiefly

through Mr. Male that the resolution proposing that the matter be discussed by the Branches had been carried. Unfortunately, however, the decisions arrived at had not been published, but at his urgent request Prof. Wooldridge, after consultation with the President, had inserted it in *The Veterinary Record* last week. It was of no use hanging it up until after the war, and it was necessary to go into the matter quickly so that it should be a guide to the profession. If the increase was agreed to a veterinary surgeon could then go with a paper in his hand to show that this was the case. He suggested that each item should be discussed separately.

Mr. MALE said it is really a matter for the local Associations, as the fees differ in different parts of the country. He thought it better if each Association discussed the matter, and if all the members agreed to the suggested increase and loyally carried it out there would be no difficulty with their clients. It was of no use passing resolutions unless all intended to carry them out. Live stock had increased so much in value, and farmers and others were in a better position now than ever before, all our expenses had increased enormously and we appeared to be the only people who had not proportionately raised their fees.

Mr. F. W. WILLETT said they understood that at Manchester and the north they would raise the fees by 50 per cent., and in other districts by 33½ per cent. He had found no difficulty in obtaining an increase of 25 per cent. by simply adding that amount to the bills.

Mr. PARKER said he had been charging 20 per cent. He thought 25 per cent. would be a fair charge, and that clients would not object. Charge them any more and he thought they would object. The price of petrol, drugs, wages, etc., had gone up so much that the fees must be increased to correspond.

The PRESIDENT: Would you increase on each item or show the added amount at end of the account?

Mr. PARKER: At the end of the account. I propose we increase the fees by 25 per cent. as compared with our pre-war charges.

Mr. BAXTER seconded, and the proposal was adopted.

*Double fees for night work.* Mr. MALE said that if they had done nothing else at that meeting of the National than to decide to charge double fees for night work they would have done a very good evening's work.

As to his own practice there had never previously been so many night calls as there were now. Farmers worked hard in the fields and did not send until they had returned home, had a cup of tea, a wash, and a walk round the case again. Then they sent round about 10 or 11 p.m. When everyone was short handed it was not fair to work them day and night; but such work was on the increase.

Mr. PARKER thought that if a double fee were charged they would be sent for earlier. He agreed that night cases were on the increase.

Mr. MALE mentioned that there was one town where the veterinary surgeons were absolutely agreed that they would not go out at night if it was a case that could be treated in the day.

Mr. Male then proposed that double fees be charged after 6 p.m. in the winter, and after 8 p.m. in the summer.

Mr. BAXTER seconded the proposal, which was agreed to.

*Fees for Examination and Castration.* The PRESIDENT proposed that the resolution of the National be amended to read, "That the *minimum* fee for a complete examination for soundness of a horse, with certificate, be £1 1s., and for partial examination 10/6, and for castration 10/6." This was seconded by Mr. F. W. Willett, and agreed to.

The PRESIDENT suggested that they obtain printed copies of what they agreed to and supply one to each

member of the Association, so that they could hang them up in their surgeries.

*Fees paid by Insurance Companies.* After some discussion, the President proposed that as the fees already recommended by the National had not yet been paid or agreed to, they refer the matter back to the National, with a view to their making some further attempt to influence the Insurance Companies. This was agreed to.

Mr. BAXTER submitted the fees that the Eagle, Star, and British Dominions Insurance Company were agreeable to give, and the meeting considered they were a good advance on other Insurance Companies, but even these did not come up to the scale suggested by the National.

*Mileage allowance.* Mr. MALE proposed, and it was carried: That Government offices be approached by the National V.M.A. to increase considerably the mileage fees allowed to veterinary surgeons, owing to the greatly increased charges for transport.

The PRESIDENT proposed: That the first three items be published as soon as possible, printed on cards, and sent to members of the Royal Counties V.M.A.

The HON. SEC. said this should be done.

#### NEW FORAGE ORDER.

Mr. MALE said the new Forage Order came into force the previous day. The Board of Trade announced that chaff fed to horses shall contain not less than one-third of straw, and no hay shall be fed without first being converted into chaff. That applied to the feeding of town horses. Personally, he was of opinion that a certain amount of long hay was absolutely necessary to keep horses in health. All the old stock of hay had been taken by the army—all the best, and only new hay was left. That would not be very good until it had had some heat on it. The feeding of horses would be a very serious matter during the coming winter. He would suggest to the Board of Trade that if only a limited amount of hay is to be given, it should be given at the discretion of the owner, and not necessarily as chaff. Many of the mangers in towns were little iron mangers. The horses threw out the hay to get down to the oats; consequently half of the hay chaff would be wasted; also, the horses, being hungry, would eat the chaff ravenously without chewing it.

Mr. PARKER: It is a decided advantage to have long hay.

The PRESIDENT said he used to be of the same opinion as Mr. Male, but the best stud of horses in town did not have a bit of long hay. They were, however, fed scientifically—one mixture for heavy horses, another for vanners, and another for cobs; that might account for the success.

Mr. MALE said he had been speaking to one of the largest firms of horse owners in the South of England, and a very scientific man fed the horses. This man had twenty years experience. When he first went to this firm he gave the horses all chaff, and it was quite the usual thing for them to have at least one case of colic a week. Now there was not a case in three months, chiefly because the horses have long hay. When he was a pupil he had experience of a very large stud of Shires containing seven champion mares, and there were constantly cases of impaction. They advised long hay, and the firm finally consented to use it. Since then it was rare to have a case of colic, while not one mare had died of impaction during a number of years.

Mr. Male's suggestion to the Board of Trade was approved.

The HON. SEC. congratulated their President on the great honour that had been conferred upon him, an honour which was thoroughly deserved. Not many members of their profession had received honours—only two of their civilian members during the war. It could

not be because they had not done splendid work for their country, but the fact remained that they had not been honoured. They were, therefore, especially pleased that their President was one of the two upon whom honour had been conferred. (Applause).

The PRESIDENT thanked them very much for their congratulations. He was very proud of the honour.

#### CALCULI.

Mr. PARKER mentioned that he attended a ten-year-old mare that had come down from town. She had been put to stud the day before, and it was thought that the horse had injured her. She would stand quietly for a time then walk about and lie down. She was swollen up and very tympanitic. He treated her, but she died two days afterwards. She was sent to the knacker, who brought back three large stones found in the flatting colon. One stone had pronounced facets where it had rubbed against another.

The PRESIDENT: You may depend the nucleus was a small piece of wire. I have seen this mostly in Corporation horses where they had been collecting the dust.

Mr. MALE said that some years ago he was interested as to whether an operation was not feasible in these cases. The thing was to get them diagnosed early enough to give them a chance. He operated in one case through the flank, and found three large calculi. He took one out, but it was impossible to get the other calculi from the large colon, as one could not get the bowel through the flank wound where, of course, the operation had to be performed. In the case of the small colon there was not that same difficulty, and he thought if it could be diagnosed early an operation might be successful.

Mr. PARKER also mentioned the case of a Shire filly which had two foals, and each of them suffered from umbilical hernia, showing the hereditary nature of the disease.

A vote of thanks to the President concluded the meeting.

G. P. MALE, Hon. Sec. and Treas.

#### The American Veterinary Colleges.

Some weeks ago reference was made in these pages to the enormous advance in the qualification of Veterinary Surgeons in U.S.A. in the last twenty years. The remarks which we quote below appear in the editorial pages of *Journal of the American Veterinary Medical Association* for May: they show that the work is steadily proceeding, and incidentally how different is their machinery for the purpose, and what a "live" interest their National Association takes in the welfare of the profession. Too often in this country practitioners are content to slide off what blame they can on the Council R.C.V.S. Across the water the men attend to the professional interests themselves.

"We have reached a point which is daily becoming more acute, where the veterinary colleges of North America, both State and private, must be so classified that prospective students who desire to take up the study of veterinary science will have some sort of a guide to aid them in choosing the particular institution from which to obtain instruction. Under existing conditions the prospective student has no means of definitely ascertaining which are accredited institutions and which are not. He usually applies to the most available college irrespective of its standing only to find when it is perhaps too late and to his sorrow that his chosen *alma mater* has a questionable standing, if any, with the profession.

Young men have come to the writer after graduation

from unrecognised colleges seeking to obtain membership in the American Veterinary Medical Association and other recognition, and have stated that they entered such institutions without knowledge and with no means of obtaining information which would in any way enlighten them as to their character and standing. They naturally assumed that so long as such colleges were operating under Government sanction by State charter that everything was as it should be.

That there is an element of injustice in all this, that should be remedied if possible, goes without saying. The big problem confronting us is to determine wherein lies the remedy. In order to start the ball rolling in this direction the following suggestion is offered: That all colleges on this continent be scored by the committee on intelligence and education of the A.V.M.A., and depending upon the score obtained each college be placed in class A, B, or C, depending upon their facilities and qualifications to give instruction. This plan has been and is being followed out by the Association of American Medical Colleges, and that it has been successful is attested by the fact that the Surgeon General has decreed that only medical men who are graduates of A or B Colleges, as classified by the Association of American Medical Colleges, can obtain entry into the United States Service. Graduates of class C colleges cannot enter the Medical Corps as officers, and boards of examiners of many states will not permit them to take state board examinations for entrance into private practice."

#### Professional differences at Reigate.

At the Reigate Town Council, on Monday night, a discussion arose out of a resolution of the Highways and Works Committee which ran: "That this Committee adheres to its former decision authorising the Borough Surveyor, in the event of a second veterinary's opinion being required, to employ Mr. C. W. Howard for the purpose, and that Mr. Squair be so informed."

Mr. C. A. Squair, the veterinary surgeon to the Corporation, had refused to meet Mr. Howard, of Dorking, in consultation respecting a matter concerning the destruction of one of the Council's horses.

In reply to Alderman Barnes it was stated by Mr. Dean they were in a pretty predicament, and he wished to move as an amendment of the Committee's resolution: "That in the event of a second veterinary's opinion being required the Surveyor may call in one." He pointed out that owing to some little difference of opinion in respect to some other business Mr. Squair was not prepared to meet Mr. Howard. Owing to what had taken place he thought if his amendment was carried it would be in the interest of the Corporation and all parties concerned. Should they dispense with the services of Mr. Squair they would be in a fix, as there was no other veterinary within six miles of the Borough. That was the first time since he had been a member of the Stables Sub-Committee that they had had any occasion to call in a second veterinary.

Alderman Farrington seconded on the ground that it was unfair to the veterinary to force him to confer with one particular man, and he did not think they should compel him to meet any one man.

Dr. Duncalfe said if they passed the amendment they gave an open order, and the natural assumption was that the officer who would be called in would be Mr. Howard.

Past events were discussed, and Mr. Priest pointed out that it was unfortunate the matter had been raised in public, and said it was assuming undue proportions. Mr. Squair was asked by the Committee to explain why he refused to meet the veterinary surgeon called in by

the Surveyor, and after hearing Mr. Squair's explanation the Committee, although by no means unanimous, were satisfied on his refusal. The matter would have ended there if subsequent statements had not been made. The matter was further investigated, and Mr. Squair's statements were found to be substantially true. The matter was one between two professional men, and the Council would be well advised to leave it at that.

Alderman Barnes said Mr. Squair had been veterinary surgeon for the Corporation over twenty years, and to his mind there had been no fault whatever to find with him. After dealing with other matter he suggested there should be added to the amendment the words: "In conjunction with the present veterinary surgeon." Mr. Squair had the Corporation affairs at heart and he had unqualified confidence in Mr. Squair's integrity and ability.

Alderman Gilbert contended that there was something underlying the whole business, and he did not like the resolution or the amendment.

Mr. Ongley argued that Mr. Squair had set the Committee at defiance as he would not meet the veterinary surgeon who had been called in. The Surveyor had charge of the horses, and he had a right to call in a second veterinary in the circumstances.

The Chairman expressed the opinion that they should not go into details, and Mr. Ongley contended they were entitled to have the whole facts placed before the Council. He proceeded to give the details, and said if the amendment was carried they would be striking a blow at Mr. Howard.

Mr. Goad: It is madness to call in two men who are antagonists.

Mr. Woodruffe thought the quarrel between Mr. Squair and Mr. Howard had nothing to do with the Council, and it was a great mistake that any member should have referred to it. They were wrong in confusing themselves to one man as they had in the district other good men who could be called in.

Alderman Ince argued if there was a quarrel between the two veterinary surgeons the Council had a right to step in. The Alderman then recited facts as he knew them, and said Mr. Squair had stated or written that if the Corporation gave him a blank check to fill in any amount he pleased he would not meet Mr. Howard. A certain statement was made which came to the ears of Mr. Howard, and it was likely to do him harm professionally. That statement went to the College of Veterinary Surgeons, and the College saw it was not a matter which concerned them as a College, and took no steps in regard to it, and that they had nothing against Mr. Howard. In fact they went further, and said that Mr. Howard was not called upon to answer any statement which had been made. Consequently Mr. Howard was completely exonerated by the College from any charge of professional misconduct. If the Corporation approved of Mr. Squair declining to have anything to do with Mr. Howard it meant that they believed the statement he had been guilty of professional mis-language. (No, no). He held no brief for either man, and all he was anxious about was that the facts should be presented to the Council.

The Chairman thought Alderman Ince had shown them good reason why they should not pass the resolution. By carrying the amendment there was no condemnation of Mr. Howard.

There was further discussion as to the wording of the amendment, which ran as follows: "That in the event of second veterinary's opinion being required another veterinary surgeon be called in by the Surveyor after consultation with the Chairman of the Committee and the present veterinary surgeon."

The amendment was carried by twelve votes to five.—*West Surrey Gazette.*

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

#### ARMY VETERINARY SERVICE

War Office, Aug. 13.

The names of the following have been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the war:—

\* \* \* \*

Capt. A. F. Castle (T.F.); Capt. (actg. Maj.) F. Chambers, F.R.C.V.C.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Aug. 10.

#### REGULAR FORCES. ARMY VETERINARY CORPS.

Temp. Lt. to be temp. Capt.:—F. Donne (July 23).

Graded for purposes of pay as D.A.D.O.S.—Temp. Capt. W. G. Stedman, Can. A.V.C., while holding the appt. of D.A.D.V.S. (May 29).

Aug. 13.

To be temp. Lts.:—Hon. Sec. Lt. C. W. Heane, late Sec. Lt. A.S.C., K. S. Simpson, T. H. Jones, H. R. Allen, J. McCunn, R. W. Down, W. A. Williams (July 23); H. F. Downie, A. L. Robertson (July 23); Hon. Sec. Lt. D. E. MacRae, late Sec. Lt. R.H.A. (T.F.) (July 24).

Aug. 14.

Capt. (Bt. Maj.) S. Black to be actg. Maj. whilst comdg. a Vety. Hosp. (Mar. 10, 1917).

To be temp. Lt.:—J. R. Rider (late temp. Capt. Yeo., T.F.) (July 23).

#### TERRITORIAL FORCE, ARMY VETERINARY CORPS.

Aug. 9.

To be actg. Lt.-Cols. while comdg. Vety. Hosps.:—Capt. (actg. Maj.) J. McArthur, Capt. (temp. Maj.) T. D. Young, O.B.E. (June 15).

#### THE BRYDON CHALLENGE SHIELD.

The Scottish agricultural papers announce that Mrs. Brydon has generously offered to renew the Brydon Challenge Shield for Clydesdales. This will be a fine tribute to the memory of the late Robert Brydon.

Major LEIGHTON, Veterinary Medical Inspector of the Local Government Board for Scotland, has been appointed to act in an advisory capacity in relation to the "organic" side of the work of the National Salvage Council in Scotland.

### An American on utility horses.

The following, a portion of a long letter to *Live Stock Journal*, exhibits a phase of the bad old practice of breeding from inferior stock; it is peculiar in that these American farmers are credited with care in the breeding of oxen and swine but neglect in the selection of their horses. The argument suggested is that the former means a direct increase in value and an early return, whereas the horses are not so readily converted to cash: but a decently bred animal would realize better than a mongrel, and it says little for the intelligence or the self-respect of the farmer—either in Britain or America—who is satisfied to breed and use such animals.

"Horsely speaking, we are a nation of careless, happy-go-lucky, unscientific breeders of horses. The thoroughbred and standard-bred trotter have become racing machines, and are too delicately constructed for any other use or purpose. The trotter is not a fixed type. On the Grand Circuit appears a mare scant of fifteen hands, narrow, spindle legged, small eared, small headed, a watch chain ornament, with the speed of the wind. The next race is won in as fast time by a gaunt, sixteen and a half hand, long legged, long eared, long headed, big footed, long barrelled ghost; the following one by a short backed, compact, arched necked, deep chested, big hearted, beautifully proportioned model for a sculptor.

Our farmers have no horses—they have no type, no consistent idea of breeding, no knowledge of what breeding consists in, no desire to produce a horse of quality, suitable for their locality and for their work. Such horses as they have are typically American, having their foundation sources in all the breeds of all the countries which have ever bred a horse. On the average farm the horses bear no relation to the work and none to each other. Feed, horse-power, and mobility are recklessly wasted. Horses of a farmer should be a valuable asset, just as his cattle, his hogs, his sheep, his turkeys, his hens, his ducks. To be such they should be bred with as much care and attention as his herds, his flocks, and his droves. The cattle, swine, and sheep raised in this country compare favourably with their foundation stock. In fact, many surpass those of the older countries. The American breeder of cattle, sheep, and hogs gives close attention, great care, and sufficient feed to go on with the breed to which he has attached himself or was born into. The small farmer, taking his cue from the big breeders, also takes pride in keeping up his herd of cattle to the highest notch of efficiency. A cattle buyer driving the country can stop at every farm where beef cattle are kept with positive assurance that the cattle will grade high. A good horse is a phenomenon. The entire township knows where such a horse is. It is to them the eighth wonder of the world. The lucky farmer that owns the good horse has no use for it because it has no mate.

True, stallion licence laws exist in twenty-one States, but many a stallion which can comply with the laws nevertheless should not be used without regard being had for the benefit produced by such use—the correction to be made upon horses which have been wandering from type. As type does not exist in America, the use of a licensed stallion is quite as haphazard in the results as though no such laws existed. The laws are designed to bar inherited unsoundness. Many sound horses are not as valuable to farmers to work as horses which have the will to work and some trifling unsoundness even inherited. He has good working knowledge of soils, machinery, and farm management. You can not 'flunk' him in protein, glucose, fibre or fat. He knows the value of all classes of manures and commercial fertilisers. He is full of sulphates and phosphates and nitrates and carbohydrates. He makes a study of the rotation of crops. He is wise about concentrates

and roughages and silage. Yet he remains in sublime ignorance of the most useful motor power needed, its care and cultivation. Any four-legged beast in the guise of a horse which will stretch a trace suffices."

### Royal Veterinary College, London.

The Duke of Connaught presided at the forty-third annual meeting of the Royal Veterinary College, London. Lord Moreton, in presenting the report, said the Governors reported that, notwithstanding the difficulties of working with a depleted staff, the educational work of the College had been carried out in a satisfactory manner, but they regretted to announce that, in spite of every possible economy, the accounts for the financial year showed an excess of expenditure over income of £1109. Owing to the unsatisfactory state of the College finances, the Governors made an application in October last to the Board of Agriculture and Fisheries for the renewal of the annual grant of £1300 towards the veterinary education provided by the College, which was withdrawn in September, 1914. The Governors were glad to announce that the Board had made a grant of £650 in respect of the academic year to 30th September, 1917.

Lord Northbrook having seconded, the Duke of Connaught said he felt very much for the Society in the difficulties under which they were working for the moment, but he supposed they were not singular. Other institutions were suffering from the effects of the war, and they must hope for the best. He warmly congratulated them on the splendid work done at the College.

Subsequently His Royal Highness commented on the splendid condition of the horses in France, and said the horses looked much better in France than in Great Britain, which brought forth the remark, "They are better rationed."

### Personal.

At the Annual Meeting Ryl. Vety. College, Camden Town, it was announced that the Coleman silver medal had been awarded to Mr. W. A. Williams, and the bronze medal to Mr. J. M'Cunn.

The marriage of Miss Grace Thompson, only daughter of Mr. Henry Thompson, M.R.C.V.S., and Mrs. Thompson, Beacon View, Aspatria, to Mr. Edward Reeve, N.Sc. of the Royal Colchester Grammar School, youngest son of Mrs. and the late Mr. George Reeve, Utttoxeter, Staffs., took place at St. Kentigern's Church, Aspatria, on Thursday, 8th inst. The Vicar, Rev. T. Hackworth, officiated. The esteem in which the bride's family are held in the district and the personal popularity of Miss Thompson brought together a considerable number of people to witness the ceremony, the church being filled. The bride was given away by her father. The bridesmaid was Miss M. Holliday, cousin of the bridegroom.

A long list of presents appears in *West Cumberland Times* of 10th inst., in which there are many familiar Cumberland names: it includes "Silver tea and coffee service—Directors of the Agricultural Co-operative Society, Aspatria."

### DISSATISFIED.

To the Editor of "The Veterinary Record."

I heartily endorse the opinion of "Dissatisfied" in your last week's issue. Some of us after four years service and invalided home, find ourselves worse off financially than when we were Lieutenants, because we are in camps built before war and, therefore, receive no allowances. It is obvious that the Council which have been credited with doing so much for us have signally failed when such conditions exist.

From another *nom de plume* of necessity,

NEMO.

## OBITUARY.

GEORGE COLLEY BLAND, M.R.C.V.S., Boston, Lincoln.  
Graduated, Lond: April, 1865.  
Mr. Bland died 8th August, aged 74.

KENNETH VIVIAN KING, Lieut. R.A.F., younger and dearly beloved son of Mr. and Mrs. G. E. King, The Vineyard, Abingdon-on-Thames, killed while acting as pilot during a bombing raid upon German Divisional Headquarters, July 30.

## Cattle Trade in Brazil.

"The Brazilian Government, it is stated, hopes to facilitate in every way, both financially and otherwise, the importation of large numbers of first-class cattle—the import of as many as 120,000 bulls is contemplated within the next ten years. Already many head of cattle (1000 Herefords) have been brought down from the States. Many have been imported from the Argentine,

and 60 zebus were recently imported from India, fetching very high prices. A syndicate is shortly to be formed to import cattle from the United Kingdom, which is to be backed up by the Government. At present it is only a question of bulls, but it is probable that the idea will expand to include the importation of cows, sheep, and pigs. The Government is willing to expend a large sum of money to help the local breeders and allow free transport by rail. It is thought by competent persons that Brazil will very soon be the most important cattle rearing country in the world. It will be to the advantage of European breeders of cattle to assist the local cattle breeder as far as possible to improve his stock in order to receive, in return, better meat."—*Board of Trade Journal*.

A pig, sold for killing purposes in Guildford Market in the last week in June, realised £30. The pre-war price would have been about £7.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1572.

AUGUST 24, 1918.

VOL. XXXI.

## SWINE FEVER.

Swine fever declined very considerably last year, especially during the second half of it. There were 2104 outbreaks, as against 4331 in 1916, and 3994 in 1915. This year we are having another great decrease; and, though it hardly seems likely that at the end the figures will halve last year's returns, they will probably fall not very far short of doing so. The decline so closely follows the adoption of serum treatment that it is not unlikely that there may be a popular tendency to connect the two as effect and cause. It would be well therefore for the profession to impress upon such farmers as need the instruction the limitations of serum treatment. When serum was introduced, we were warned not to over-estimate its capacity; and a similar warning has recently emanated from the same source.

In the Annual Report of Proceedings under the Diseases of Animals Act for 1917, the lull in swine fever is considered. Here it is stated definitely that "since serum treatment can only be employed when outbreaks of the disease have actually occurred, its adoption is not calculated to operate in the direction of reducing the number of outbreaks," and it is added that "other causes must be sought" to explain the rapid fall of the disease. The Board's explanation is that "the prime factor in the reduction of the number of outbreaks is that, for reasons due to the general position in the country at large, pigs are not now moved about either in the same numbers or to the same extent as is usual in times of peace, the chances of infection being spread are proportionately reduced." It is not asserted, of course, that this is the sole factor; and very probably it may not be. In view of the many strongly marked and unaccountable ups and downs which swine fever has shown in the past, we can hardly deny that factors which we have never yet recognised must exist to influence its rise and fall. Still, there is no doubt that the Board's view of the main reason for the present position is correct.

Our most hopeful line of action against swine fever appears to be a combination of general restriction of movement with serum treatment during outbreaks. War conditions are imposing this restriction of movement upon us at present; and it will probably be continued afterwards to as great an extent as trade will permit. Our present business is to see that the fullest possible use is made of serum treatment. This can best be done by working for the early reporting of outbreaks, but without claiming for the serum results which it does not produce. Obviously it cannot eradicate swine fever; but its proper and timely use will immeasurably decrease the losses from the disease.

## HOT AIR IN THE TREATMENT OF PARAPLEGIA IN THE DOG.

Bouchez, in 1914, reported this case to the Central Society of Veterinary Medicine. The subject was a bull-bitch, which, when two years old, presented a complete posterior paraplegia, with fecal and urinary incontinence, as a result of distemper. Recovery was obtained; but a persistent emaciation of the posterior third of the body remained. When three and a half years old, during the winter, the bitch contracted a chill, and the next day she could not raise the posterior part of the body.

Ordinary treatment was employed for a week with little result. Bouchez then commenced treatment by hot air, by means of Rupalle's apparatus, which works with alcohol, and is provided with a thermometer graduated from 50° C. to 225° C. He gave two applications of hot air daily upon the lumbar region, each lasting twenty minutes; with the air first at 126° C., afterwards raised to 130° C., and continued at that temperature till the end of the application.

After the fifth application the bitch could stand on the hind limbs for a few moments, the sphincter recovered its tone, and the case began to look hopeful. The treatment was continued, always under the same conditions, and improvement was progressively accelerated. After nine days of treatment the recovery was complete.

Seven months later, in consequence of a bath, the bitch again contracted a chill. Paresis of the right hind limb, with absolute impotence of the left one, appeared. The right limb recovered its normal functions after three applications of hot air; and the left one after ten applications.—(*Revista de Higiene y Sanidad Veterinaria*).

## CONTAGIOUS AGALACTIA OF GOATS IN ALGIERS.

E. Sergent and G. Roig, in the *Bulletin de la Société de Pathologie Exotique*, give an account of studies which they carried out in the Pasteur Institute of Algiers upon an epizootic of caprine contagious agalactia which they observed in 1908. At that time Sergent was called to visit, in the neighbourhood of Algiers, a flock of goats comprising 450 head, in which, in a week, 70 ewes and some males, with some young animals, were attacked. Three or four kids died daily; and in two months 19 ewes and 105 kids had died. This disease, though not frequent, was observed ten years before in Algiers by Banguil in the towns of Guergot and Kerrata.

During this epizootic the authors were able to isolate, from the milk of all the milking animals, a

pure culture of a microbe which, when inoculated into female goats, produced no symptoms of the disease. This fact confirms the discovery of Celli and Blassi, who, in 1906, attributed the specific causation of the disease to an ultra-visible virus. The microbe found by Sargent and Roig was not pathogenic, like the pyobacillus discovered by Carré in 1912; it was more similar in its characters to the Preisz-Nocard group. Some microbes of the same group are encountered in diverse serious affections of the sheep. Their pathogenic function is not well elucidated.

The authors give the following description of the epizootic. In kids, the appetite was almost absent, the limbs were drawn under the body, the head was slightly drooped, and the hairs were bristling. Sometimes the animals were not able to stand, and fell; and convulsions were not rare. Death generally supervened at from the second to the fourth day. In exceptional cases, the temperature reached 104° F. Sometimes, in the course of the disease, severe symptoms of lameness appeared. Post-mortem examination gave negative results. In adults, the disease made less ravages than in young animals; the general symptoms were more vague; and the illness developed in a chronic form. The appetite diminished slightly; and the temperature oscillated between 102° F. and 102.5° F.

The lesions were encountered principally in the mammary glands. Sometimes a mammary gland and an articulation were attacked simultaneously.

The gland was inflamed; the lacteal secretion diminished greatly; and the milk, collected in a flask, divided into two very distinct portions. The inferior part, which was one-third to two-thirds of the total volume, was a dirty white deposit; the portion floating above this, which frequently reached two-thirds of the total volume, was a dirty white liquid, sometimes reddish. The milk had an alkaline reaction. It coagulated at 100° C., and, mixed with normal milk, coagulated it at the same temperature; it preserved this property after passing through a Chamberland F filter. At the end of fifteen days the lacteal secretion ceased almost completely. Post-mortem investigations gave negative results.

The authors attempted to reproduce the disease in goats by inoculating milk into the teat, into the peritoneum, and under the skin, by the ingestion of milk, and by cohabitation. They also inoculated small laboratory animals with infected milk. One goat, an ewe, was infected by cohabitation; but the only other experiments which gave positive results were the inoculations of milk. Inoculation of the blood of infected animals neither transmitted the disease nor had any vaccinating action. Inoculation of milk subcutaneously and intraperitoneally infected goats with certainty; but intraperitoneal inoculation did not infect the small laboratory animals. The virus became attenuated during the passages. Ingestion of infected milk did not reproduce the disease.

In the natural disease, mammary lesions were constant and articular lesions frequent; but ocular lesions were not observed. Non-lactiferous animals

only presented articular symptoms. In the experimental disease both the mammary and articular lesions were constant; and ocular lesions were observed in two out of thirteen cases.

The above-mentioned bacillus related to the Preisz-Nocard group was found constantly in the milk, but not in the blood. The authors regard it as a symbiosis of the invisible virus discovered by Celli and Blassi.—(*Revista Veterinaria de Espana*).

W. R. C.

## Royal College of Veterinary Surgeons.

### SPECIAL MEETING OF COUNCIL.

A Special Meeting of Council was held at the College, 10 Red Lion Square, London, W.C., on Friday, the 16th inst., when the following members were present:—Mr. F. W. GARNETT, President, in the Chair; Maj.-Gen. L. J. Blenkinsop, D.S.O.; Dr. O. C. Bradley; Messrs. J. C. Coleman, J. Dunstan; Prof. S. H. Gaiger; Messrs. W. J. Mulvey, T. S. Price; Prof. E. S. Shave; Mr. S. H. Slocock; Sir Stewart Stockman; Dr. J. Share-Jones, Mr. R. C. Trigger.

Apologies for absence were received from Major J. Abson; Messrs. G. A. Banham, W. F. Barrett, J. H. Carter, A. Lawson, J. McL. McCall; Sir J. M'Fadyean; Messrs. W. Packman, H. Sumner; Major-Gen. H. Thomson; Mr. S. Wharam.

The PRESIDENT explained that he had called the meeting to consider a letter from the Local Government Board with regard to the establishment of a Special Veterinary Tribunal. Acting on the instruction of the Council at its previous meeting, he had submitted the following statement of the present position to the War Office on July 12th:—

#### SUPPLY OF VETERINARY SURGEONS FOR THE ARMY.

The present situation with regard to the supply of duly qualified Veterinary Surgeons to meet the requirements of the Army Veterinary Service is as follows:—

There are on the Register of Veterinary Surgeons at date July 1st, 1918, 3350 members, of whom at least 350 are in practice outside the United Kingdom.

There are thus in the United Kingdom	3000
Of these, members over 60 years number	
approximately	240
Members practising other professions	12
Practising in Ireland	343
Total in round figures	600

2400

The Army Veterinary Service employs in	
either a civil or a military capacity	1200

Leaving in practice in Great Britain	1200
--------------------------------------	------

Of these it is estimated that one-tenth, or 120, are under the old military age.

So large a proportion of Veterinary Surgeons has already been taken away from civil practice that it has now become a matter of extreme difficulty equitably to decide on the relative claims of the War Office and of civil practice on the services of any Veterinary Surgeon.

During the past four years the Council of the Royal College of Veterinary Surgeons has used every means in its power in the endeavour to secure the services of as many qualified men as possible for the A.V.S. Without further powers it feels itself incapable of suggesting ways

and means to meet the still urgent need for qualified Veterinary Officers fit for service overseas.

Owing to the enlistment of Veterinary Students and to the effect of the Proclamations of April 20th and June 4th—calling up all students between the ages of 18 and 23, and over Grade III—the supply of graduates is fast diminishing almost to vanishing point. On the other hand, there are still in active practice in Great Britain—apart from Ireland—at least 120 young men who are at present exempted from military service by Local Tribunals on the ground of the national importance of their work. It has been impressed upon the Tribunals with much truth that no substitutes can be found. There are, however, a number of Veterinary Surgeons now serving overseas who are considerably over military age, and who require to be relieved from the strain of military duty. These could, if so relieved, act as substitutes for the younger men now exempted, but it is obvious that the equitable carrying out of such substitution could only be performed by one central Tribunal.

It is therefore suggested that the Local Government Board in pursuance of the powers given to it by the Military Service Acts, 1916-18, and under the provisions of the Military Service Regulations, 1918 (R. 185) Part III, Sec. 54, should appoint a special Tribunal to deal with all applications for the grant, renewal, or review of certificates of Exemption to Veterinary Surgeons in Great Britain.

The special Tribunal, to be called the Veterinary Tribunal, should consist of such number of members representative of the Veterinary Profession as the President of the Local Government Board may from time to time appoint.

As the Royal College of Veterinary Surgeons is the only body empowered by Act of Parliament and Royal Charter to deal with the education, examination, and registration of Veterinary Surgeons in the United Kingdom, and as the Council of the College is elected from year to year by the votes of the members of the College who constitute the Veterinary Profession, it is suggested that ten members of the Council, appointed *ad hoc*, would form a representative Veterinary Tribunal. Representatives of any Government Departments concerned could also have seats on the Tribunal.

The Veterinary Tribunal should have similar powers and duties as are prescribed for other special professional Tribunals. It should be empowered to grant certificates on occupational grounds, but only on condition that the Veterinary Surgeon shall undertake such professional service and under such conditions as the Director-General of National Service may, after consultation with the Veterinary Tribunal and in concert with any Government Department concerned, from time to time deem best in the national interests.

It should also have the power to require from the Army Veterinary Department from time to time a list of such officers now serving overseas as may be available for release from military duty. It should be the duty of the Tribunal to make arrangements for the substitution of such released officers in the place of any Veterinary Surgeon whose certificate of exemption may be withdrawn, in cases where this may appear to be necessary.

The matter was then taken up by the Army Council and brought before the Local Government Board. A conference was held at the Local Government Board on Friday, July 26th, at which the following representatives were present:—Mr. I. G. Gibbon, C.B.E., Local Government Board; Maj.-Gen. Ellison, Dep. Q.M.G.; Maj.-Gen. Blenkinsop, D.G., A.V.S.; Mr. F. W. Garnett, President R.C.V.S.; Sir Stewart Stockman, Bd. of Agric.;

Maj. Corlette, Bd. of Agric. Food Production Dept.; Mr. H. R. Selbie, Bd. of Trade, Controller of Horse Transport; Mr. J. R. Wardlaw Burnet, Ministry of National Service; Mr. P. J. Rose, Scottish Office; Mr. James Wood, Scottish Bd. of Agric. The whole position was carefully considered, and on the representations of the Army Council the Local Government Board had agreed to set up a Special Tribunal empowered to deal with the grant, renewal, or review of Certificates of Exemption to or held by duly qualified Veterinary Surgeons in Great Britain. The Board now asked the Council to nominate 12 members of Council and 8 members of the profession outside the Council, from which the President of the Local Government Board would appoint 8 members of Council and 4 outside members to form the Special Tribunal.

After discussion, it was proposed by Sir Stewart Stockman, and seconded by Mr. S. H. Slocock: "That the Council accept the invitation of the Local Government Board to nominate 12 members of Council and 8 members outside the Council, from which the Board is to appoint the Special Veterinary Tribunal of twelve members."

The motion on being put to the meeting was declared carried.

The PRESIDENT stated that he and the Secretary had had an interview at the Local Government Board and that the opinion had been expressed that it would be advisable in choosing names to arrange that there should be a sufficient number of members chosen from Scotland and the North of England to ensure that a quorum of three would be obtainable at sittings of the Tribunal held in Scotland. It was also desirable to take into consideration the geographical distribution of the members nominated.

The President of the Local Government Board had fixed the number of members of the Tribunal at 12, including the Chairman, who, it was suggested, should be the President of the Royal College of Veterinary Surgeons. Mr. Garnett stated that he had agreed to act in that capacity, and would attend as far as possible all meetings of the Tribunal wherever held.

The Council then proceeded to the selection of names, and ultimately the following list was agreed upon, the Secretary being instructed to obtain the consent of the members not present, and to forward the list to the Local Government Board:—

#### *Twelve Members of Council:*

G. A. Banham, F.R.C.V.S., Cambridge.  
Dr. O. Charnock Bradley, M.D., D.Sc., CH.B., M.R.C.V.S., Edinburgh.  
J. Clarkson, M.R.C.V.S., Garforth.  
J. C. Coleman, M.R.C.V.S., Swindon.  
J. Dunstan, M.R.C.V.S., Liskeard.  
Prof. S. H. Gaiger, F.R.C.V.S., M.R.S.I., Glasgow.  
Frank W. Garnett, C.B.E., J.P., M.R.C.V.S., Windermere.  
Sir J. M'Fadyen, LL.D., M.B., B.Sc., C.M., London.  
W. J. Mulvey, J.P., F.R.C.V.S., London.  
Dr. J. Share-Jones, D.V.Sc., M.Sc., F.R.C.V.S., Liverpool, and Acrefair, N. Wales.  
S. H. Slocock, F.R.C.V.S., Hounslow.  
P. Wilson, M.R.C.V.S., Lanark.

#### *Eight Members of the Profession outside the Council:*

Hugh Begg, F.R.C.V.S., Lanark.  
J. Brown, F.R.C.V.S., Invergordon.  
H. J. Dawes, F.R.C.V.S., West Bromwich.

### Rinderpest in East Africa.

A few weeks back, allusion was made in a Report to a threat of Rinderpest coming south from German East Africa, and the depletion of the S. African veterinary staffs to meet it. The following abstract of reports by Mr. C. E. Gray, P.V.O. Union of S. Africa, of the expedition to check the invasion is taken from *Tropical Veterinary Bulletin*. German E. Africa is a long way from Britain, but the possibility of a visitation, as a legacy from the long war, is by no means a remote one.

"In these reports an account is given of the measures taken to prevent the extension of rinderpest in a southward direction from German East Africa into the Nyasaland Protectorate and Northern Rhodesia. The area in which operations were undertaken embraced the region lying just north of the boundary, that is between the northern end of Lake Nyasa and the southern end of Lake Tanganyika and south of the Livingstone range of mountains and Lake Rukwa. Before the arrival of the expedition for the control of the disease under Colonel Gray the Nyasaland and Northern Rhodesian authorities set up a barrier against the rapid spread of the disease southwards by removing all cattle from a belt 10 to 20 miles wide south of the German boundary. A few outbreaks had been located south of the Livingstone range and thus it was resolved to clear the disease from the affected localities by the adoption of simultaneous inoculation methods, and also immunise by the same method all cattle running in a belt of country about 35 miles wide lying north of the German boundary.

Inoculation camps were thus established at various places in order to carry out this plan but at first the disease appeared to show a tendency to die out naturally, and the native cattle of the districts affected appeared to possess a high degree of natural immunity. Moreover, the experience gained at the inoculation camps showed that certain complicating factors of a somewhat serious character had to be reckoned with when working on a large scale, which were not anticipated when the establishment of a belt of immune cattle along the southern border of this territory was originally contemplated. The original scheme was thus abandoned and instead of it measures were taken to guard the New Langenburg district against the introduction of the disease from the other side of the Livingstone range where rinderpest is always more or less enzootic.

The most important complicating factor was the appearance of a large mortality from East Coast fever among the cattle collected at the concentration camps. The mortality from this disease did not begin until the animals had been inoculated with rinderpest blood and serum, and, although the occurrence of ordinary red-water as a complication in outbreaks of rinderpest, where the vitality of the animals has become depressed owing to the inoculation, is well recognised, a similar phenomenon has not yet been proved to take place in the case of East Coast fever. Inoculation experiments were thus carried out in order to elucidate this problem and these 'appeared to show that such complications were likely to occur, although the mortality therefrom might be negligible, most of our animals showing microscopic evidence of the revival of East Coast fever infection by the appearance of Koch's bodies in their blood

whilst undergoing reaction to rinderpest inoculation. None of these died, however, although several control animals inoculated at the same time with rinderpest virus alone and unprotected with serum succumbed after showing during the course of their illness that East Coast fever organisms had again become active.'

These experiments appear to prove that the bad results obtained at one of the concentration camps (Old Utengule) were chiefly due to the movement of cattle susceptible to East Coast fever into an area where that disease was enzootic, for purposes of inoculation, rather than to a serious breakdown in the immunity of animals reared on East Coast fever veld. The records of the German authorities pointed to a very high mortality from East Coast fever among the cattle of this district.

However, as the result of the inoculation rinderpest appeared to have been brought speedily under control. Investigations were then carried out to ascertain the prevalence of rinderpest immediately north of the Livingstone range of mountains and towards Lake Rukwa and determine whether the mountains could serve as an efficient barrier against the southward spread of the disease. Only one small outbreak was detected and this was dealt with by serum inoculation. Elsewhere the disease appeared to have died out.

Unfortunately, however, in the meantime rinderpest re-appeared in the New Langenburg district south of the mountains and the history of the outbreak showed that it had originated owing to the unauthorised movement of cattle while undergoing a reaction subsequent to inoculation, and it assumed serious dimensions owing to the concealment by the natives of the first cases that occurred. This was dealt with by the use of serum alone, but later a number of other outbreaks were detected and work had thus to be resumed by adopting the simultaneous method of inoculation and carefully guarding the area in which operations were undertaken.

Gray then adds a few remarks upon the methods employed where large numbers of cattle had to be inoculated in order to effect economy of time and labour with less fatigue to operators working under a tropical sun. The short crush method adopted by G. Garden was found to answer this purpose best.

'In the short crush method a crush capable of accommodating two animals only is erected, width at bottom being twelve inches, the uprights inclining outwards at an angle which increases the width to two feet six inches, at a height of three feet above the ground. The crush is provided with two sets of slip rails, the one set at the exit from the crush, the other set five feet six inches further back, there being a stout post sunk in the ground in front of the exit, round which the head rope can be hitched in the event of an animal proving refractory. The animals are roped individually by the owner in the kraal connected with the crush, the rope is passed forward along the crush, the head drawn up to the front slip rail and held there by three or four boys, while the slip rails are put in behind it. The inoculators stand one on either side of the crush, and as the animal is secured, they inoculate it simultaneously, brand it, liberate it, and stand ready for the next. With tractable animals, and natives who handle the ropes and bring the animals forward quickly, it has been found possible for four operators working at two crushes, to inoculate over eighteen hundred head in a day with much less effort than would be required to handle a similar number by casting them and walking from one animal to another.'

Over 11,000 cattle were inoculated at the two new stations; the reactions in many cases were well-marked and although fatal cases were observed in which East Coast fever infection had apparently been revived by inoculation the mortality due to inoculation was not more than one-half per cent. Two or three small centres

were found which were stamped out by the use of serum alone.

Unfortunately again, however, rinderpest made its appearance close to the Nyasaland border owing to movement of a couple of calves out of an infected area by a native headman. This fresh focus of infection lay in the centre of a district containing about 20,000 head of cattle and situated around a route of considerable military importance. Mention is made at the close of the report that the work of inoculating all cattle in the belt of country involved by this fresh outbreak had just been completed and the author then entertained the hope that there was a fairly good chance of keeping the disease out of Nyasaland, especially as intercourse with that country had been entirely stopped along the Songwe on account of the presence of bubonic plague at Karongo on the other side of the river.

The work had to be carried out under difficulties owing to the diminished number of personnel due to sickness and military requirements.

SOME CAMEL-FEEDING EXPERIMENTS.\* By H. E. CROSS, M.R.C.V.S., D.V.H., A.S.C., Camel Specialist, Sohawa, Punjab. [Abridged.]

Our knowledge regarding the quantity of fodder that a camel requires is very limited, and no experiments have, so far as I am aware, been carried out to determine the quantity of fodder that a camel requires to keep him in condition. Requests have been frequently made by the military authorities for information regarding the quantity of fodder that should be given to camels.

The only camels available for the purpose of feeding experiments were medium-sized camels suffering from surra (7-14 years old). It would have been much more satisfactory to carry out the experiments with non-surra-infected camels, but this it was not possible to arrange.

The camel can be trained to eat almost anything, and the fodder on which he feeds varies greatly in different parts of the country. The Punjabi camelmen prefer browsing to stall-feeding, and undoubtedly the camel thrives well if sufficient time is allowed, and the browsing is of good quality. When the browsing is poor or sufficient time is not available, fodder such as *missa bhusa* (pea straw), *moth bhusa* (*Phaseolus aconitifolius* straw), and *mung bhusa* (*Phaseolus mungo* straw) and, when in season, green *tara mira* (*Eruca sativa*), green *moth* (*Phaseolus aconitifolius*) and green gram are fed to camels. As a rule the camelman does not feed gram to his camels, he is unable to afford it. *Chitta bhusa* (wheat straw) and *Phaliyat* (*Eruca sativa* stalks) are occasionally fed. Camelmen however do not like wheat straw as a camel fodder, and *Eruca* stalks have probably little nutritive value. Without doubt a camel thrives best on fodder and browsing that he has been accustomed to. A camel brought to a district in which the browsing differs from that to which he has been accustomed, or when stall-fed on fodder that he has not been used to, will fall off in condition; but if he is carefully looked after and only lightly loaded to start with, he quickly becomes accustomed to the change and will rapidly regain his condition.

Experiments regarding the quantity of fodder a camel will eat were carried out with the following:—

- 1 Gram and *missa bhusa*.
- 2 *Missa bhusa* without grain.
- 3 Gram and *moth bhusa*.
- 4 *Moth bhusa* without grain.

- 5 Barley, turnips, and *moth bhusa*.
- 6 Gram and green *tara-mira*.
- 7 Green *sarson* (Indian colza).
- 8 Oat hay and ordinary hay.

The camels got poor browsing during the day: the fodder was given in the evening at about 5 p.m. The quantities are given throughout in pounds.

#### 12 of Gram and *missa bhusa*.

Average = 12 gram and 20.6 *missa bhusa*. The gram was fed first and 40 *missa bhusa* was given to each camel; and the amount left over next morning was weighed.

[Eight camels were used: the test feeding lasted six days. The gram was eaten in every case. The *missa bhusa* eaten per animal varied from 8 to 35 per diem, and the averages from 13 to 27.1 for the six days.]

#### 6 Gram and *missa bhusa*.

Average = 6 gram, 23.1 *missa bhusa*. The gram was fed first and 40 of *missa bhusa* was given to each camel; the amount left over next morning was weighed.

[Eight camels, fed for 25 days; the *bhusa* varied per camel per day from 10 to 35, and the averages for the whole period from 18.4 to 26.1.]

#### *Missa bhusa*.

Average = 24.9 *missa bhusa*. 40 of *missa bhusa* was given to each camel in the evening and the amount left over next morning was weighed.

[Six camels, fed for 10 days. The amount eaten per camel per diem ranged from 16 to 39; and the averages from 22.5 to 27.2.]

#### 4 Gram and *missa bhusa*, two-year-old camels.

Average = 4 gram and 14.7 *missa bhusa*. The gram was fed first and 30 of *missa bhusa* was given to each camel; the amount left over next morning was weighed.

[Three camels (two males, one female), fed for 12 days. The *missa bhusa* per camel per day varied from 6 to 22; the averages for the period were 16.8, 14.9, 12.5 respectively.]

#### 6 gram and *moth bhusa*.

Average = 6 gram and 26.7 *moth bhusa*. The gram was fed first and 50 of *moth bhusa* was given to each camel; the amount left over next morning was weighed.

[Six camels, fed eight days. The *moth bhusa* eaten per camel per day ranged from 18 to 40; the averages for the period 21.25 to 31.5.]

#### *Moth bhusa*.

Average = 29.9 *moth bhusa*. 50 *moth bhusa* was given to each camel, and the amount left over next morning was weighed.

[Nine camels, fed 11 days. *Moth bhusa* eaten per camel per day varied from 12 to 44, the averages for the period 23.5 to 33.8.]

#### 5 Barley, Turnips, and *Moth bhusa*.

Average = 5 barley, 26.6 turnips, and 26.4 *moth bhusa*. The barley was given first, then the turnips, and then the *bhusa*. The camels did not relish the barley; only 20 of turnips were given to each camel the first two days, 30 the other four days; 50 of *moth bhusa* was given to each camel, and the amount left over next morning was weighed.

[Five camels, fed six days. The barley and turnips were cleared, *moth bhusa* varied from 15 to 40 per day, and the averages for the period 24.1 to 28.]

#### 6 Gram and Green *Tara-mira*.

Average = 6 gram and 66.1 green *tara-mira*. The gram was fed first, and 100 of green *tara-mira* was then

\* Bulletin No. 77, 1918, Agricultural Research Institute, Pusa. [Received for publication on 11th May, 1917.]

given to each camel, and the amount left over next morning was weighed.

[Seven camels, fed 24 days. Tara-mira varied from 35 to 86 in daily ration; and the averages for the period from 60.1 to 71.3.]

#### Green Sarson.

Average (four days) = 154.9 green sarson. On the fifth day the faeces became soft, like cow dung.

[Five camels, fed seven days. The ration of 50, 100, 150, given first three days was cleared. Other four days 200 was given. Daily amount varied 115 to 192. Averages for the four days 141 to 168.2.]

#### Oat Hay.

Several camels were fed on oat hay. The oat hay was at first mixed with an equal quantity of missa bhusa, the quantity of the latter being daily reduced until finally only oat hay was given. The camels did not relish it, and the largest quantity eaten was 17. The oat hay, however, was of poor quality.

#### 6 Gram and Hay.

Six camels were starved for one day and then fed on 6 of gram and hay. The amount eaten is given in the following table. For the first three days they were given no grazing, for the remaining three days they were allowed to browse during the day.

Average = 6 gram and 16.2 hay.

[Six camels, fed six days. 35 of hay was given, the daily amount varied from 8 to 31. The averages for the period 12.3 to 19.0.]

Maximum quantity of fodder eaten, in addition to poor browsing. All quantities given in pounds.

- 12 gram and 35 missa bhusa.
- 6 gram and 35 missa bhusa.
- 39 missa bhusa.
- 2 gram and 22 missa bhusa (two-year-old camels).
- 6 gram 40 moth bhusa.
- 45 moth bhusa.
- 5 barley, 30 of turnips, and 40 moth bhusa.
- 6 gram and 86 green tara-mira.
- 192 green sarson.
- 6 gram and 31 hay.

#### Summary.

The average quantity of fodder eaten, in addition to poor browsing, was as follows:—

- 12 gram + 20.6 missa bhusa.
- 6 gram + 23.1 missa bhusa.
- 24.9 missa bhusa.
- 4 gram + 14.7 missa bhusa (two-year-old camels).
- 6 gram + 26.7 moth bhusa.
- 29.9 moth bhusa.
- 5 barley + 26.6 turnips + 26.4 moth bhusa.
- 6 gram + 66.1 green tara-mira.
- 135.4 green sarson.
- 6 gram + 16.2 hay.

#### Conclusions.

Taking into consideration the fact that these experiments were carried out on camels suffering from surra and doing no work, it is probable that healthy camels on hard work would eat very much more. The experiments, however, show that the present Government ration of 16 of a mixture of wheat and missa bhusa per camel is insufficient.

[This experiment appears to be distinctly useful, inasmuch as it gives a general indication of quantities necessary in rationing camels—a very necessary knowledge in dealing with numbers, as in army work—and a definite evidence that the present government allowance shows a discrepancy.

Examining the tables—omitted in our reprint—one cannot help feeling that averages are not a scientific

instrument, but only a rough and ready means of establishing a working hypothesis. This can be very readily seen in the reports of sale-yard results in the Live stock columns of agricultural papers. Taking one of the tables given in the Bulletin, which shows 6 lb gram, 100 lb Tara-mira was fed to 7 camels for a period of 24 days, we get the return of 168 days feeds of tara-mira (the gram was always cleared) the lowest of which was 35 and the highest 86 lb. Four of these camels ate on the average 69 to 71 lb daily in the period: the other three about 10 lb less. Of these 168 daily feeds 59 were between 60 and 70, and 63 between 70 and 80 lb—that is 122 of the 168 were between 60 and 80 lb, and from 56 to 60 lb there were another 16. So that the average given (66.1 lb) is rather under than over: or to put it another way, the smaller feeds have pulled down the average of three-fourths of the feeds recorded in this particular experiment.]

#### Special (Veterinary) Tribunal.

As we go to press, intimation is to hand, by courtesy of the Secretary L.G.B., that the following gentlemen have been appointed a Special Tribunal (Veterinary Tribunal) for dealing with any application on and after 28th August:—F. W. Garnett, G. A. Banham, Hugh Begg, O. Charnock Bradley, J. Clarkson, H. J. Dawes, Sir J. M'Fadyean, W. J. Mulvey, S. H. Slocock, J. Willett, P. Wilson, W. Woods.

ACCIDENTALLY KILLED—Capt. W. A. Morrin, attd. R.G.A.

DIED OF WOUNDS—Maj. C. B. Seelenmeyer, Aust. A.V.C.

### New Forest Ponies.

It is a great characteristic of the New Forest pony to be always gay and on the alert; they are generally extremely good-tempered, and very seldom do you come across a sulky pony. It is a rare thing to get business and fun together: in the New Forest it is possible to get them combined by being a breeder of ponies. October, November and December are the months when the rounding-up of the suckers, yearlings, and other ponies takes place, and the agisters are busy during this part of the year tail marking.

The suckers more especially are sent to Brockenhurst annual sale of ponies in October, Martin's Town Fair in Dorsetshire in mid-November, or at Ringwood in December, or as yearlings eight months later to Lyndhurst Fair, or Bridford Fair in August. The rounding-up is as good as a day's hunting, if you have a wild pony and have a forty or fifty minutes' gallop and sit down in your saddle and go. Commoners, four or five together, arrange with the agister in their district to have a day's rounding-up.

The meet is arranged—and on arriving another meet is arranged; all take a beat and hunt for ponies in their haunt. If ponies are found and are quiet, the commoners still go to the second meeting-place, and it is then arranged where to drive ponies in some forest pounds or farm.

If on finding ponies, and they are wild and gallop off, the funder "Halloos," and the remainder come to it, and ponies are driven in shape of a V, one behind and two on each side if five are out.

The suckers are haltered, and two, as a rule, are tied together, and you might meet half-a-dozen being driven home in this way after a good day. The more up-to-date way is to take colts back in wagons and carts, owing to the danger of motor-cars, especially at night. Mares that are haunted—well, their stock of mares—are generally saved, branded, and tail-marked by the agister. The good horse colts are kept for entires, and in April about 160 entries are shown at Lyndhurst in four classes—viz., yearlings, two-year-olds, three-year-olds, four-year-olds, and upwards. The Board of Agriculture has supported the show by giving ten premiums in class for four-year-olds and upwards. Three challenge cups are given, one in four-year-old and upwards, by Sir Edward Hulse, which has been won for the last three years and was won outright in 1915 by Mr. S. Barrow, Gore Farm, New Milton, Hants. This pony is a pure Forester, and has been the best pony that has competed for the past three years. The Cecil challenge cup is given by the late Lord Arthur Cecil's two sons—Mr. A. W. Cecil and Major R. Cecil—for four-year-olds, and the Boldre challenge cup is given by Mr. F. Perkins, M.P., for three-year-olds. Lady A. Cecil gives two special prizes, and the National Pony Society four silver medals, one for each class.

As an encouragement, cups are very much needed for two-year-old and yearling, and the competition in these classes would be greater. Many farmers in the counties of England do not realise the good a pony will do to eat off the rough grass where cow stock have been grazing, besides being a good investment. Ponies going away on good pasture will get to 14 hands. A mare that was bred from a Forest mare above 13 h. 3 in., and the sire a thoroughbred horse, grew to the height of 15 hands, and won the open jumping class at Burley in August, 1914, and two days after mobilised and had twelve months' work with a cavalry regiment.

There is not the slightest doubt that for hardness and durability, a military horse can be bred from a New Forest pony if good keep is provided.

T. STOVOLD,  
Hon. Sec., New Forest Pony Assn.

### OBITUARY.

LEONARD BAKER COLE, Capt. A.V.C.

Graduated, Lond: Dec., 1907.

Capt. Cole died on active service.

### A Vegetable Milk.

Some of our readers may remember that this suggestion of a milk substitute from soya beans was noticed in our pages some 8 or 10 years ago—possibly more. The idea did not materialize, and so far as we know, nothing has since been heard of it. The following appeared in *The Lancet* not long since, "From a correspondent." It remains to be seen whether present conditions will result in the use for food purposes of some of the "hundreds of thousands of tons imported."

"In these days of agalactia any reasonable substitute for milk is certain of a welcome, so that particular interest attaches to the soy bean, an alimentary plant grown on a very large scale in China, and imported into this country by hundreds of thousands of tons annually for the sake of the oil it contains, which is utilised in the manufacture of soap, margarine, etc. More interesting from the alimentary point of view is the fact that it can be made to yield a substitute for milk, which in respect of appearance and composition is wellnigh indistinguishable therefrom. The process is simple. Five ounces of the bean are soaked overnight in a quart of cold water; it is then coarsely ground, mixed with the water in which it has been soaking, and filtered through muslin. The result is a milky fluid with a rather strong smell of haricot bean, which disappears after it has been raised to boiling point. Infants take it readily, and, mixed with tea or coffee, the taste is imperceptible. Fresh soy bean milk has a faintly acid reaction; it is quite homogeneous under the microscope, and its physical properties are those of cow's milk; rennet causes it to curdle, lactic acid germs cause it to undergo lactic acid fermentation. When boiled it "rises" like ordinary milk and forms a pellicle on the surface. Its composition is: Casein 3.13 per cent., fats 9.89, but it lacks carbohydrates, a shortcoming which can easily be remedied. As the fatty constituent is an oil, butter cannot be made from soy bean milk, but it can be made to provide cheese (120 grams of the bean yields 184 grams of cheese), and the cheese can be made to resemble any of the popular cheeses in the market; it is merely a question of employing the proper flavouring ferment. Soy-bean milk can be retailed at 3 centimes a litre. The residue, after making milk, is still very rich in alimentary principles, and can be worked up into very palatable "almond" cakes or biscuits. Being practically free from starch, these cakes are specially suited for consumption by diabetics. Roasted, the bean provides a colourable imitation of coffee, just as do barley and oats, to what a satisfactory degree only those who make use of these substitutes will understand." The soy bean and its derivatives are very rich in phosphates,

so that infants reared on the milk are never likely to develop rickets.

Unfortunately the soy bean does not take kindly to the English climate, but it grows freely in China, where it is indigenous, in southern France, in Algeria, and in many parts of the United States, where the plant is used extensively for fodder. There are a number of varieties possessed of special qualities according to climate and the object in view—for example, oil, or milk, or cattle food. A practical idea of its alimentary value may be formed by contrasting the cost of this as compared with other albumins: 100 grams of albumin, at the before-the-war prices, would cost—from egg 1s. 8d., from meat 1s. 4d., from pork 8d., dried peas 3d., and from soy bean 2d. The bean contains four times as much mineral constituents as meat, and is twice as rich in phosphoric acid.

The following shows a comparative analysis:—

	Water.	Nitro. Constnts.	Fats.	Starch.	Cellu- lose.	Ash.
Soy Beans—						
Maxim.	11.30	38.41	14.80	32.11	6.20	5.20

Maxim.	15.30	26.51	1.50	58.03	7.86	3.26

#### Losses from tick infestation.

In a short article in *Queensland Agric. J.*, by E. E. D. White, which is held to convey "the opinions of an experienced stockman on an unfenced holding carrying 17,000 cattle and working eight dips" in North Eastern Queensland, it is stated that:—

"The losses among cattle due to ticks (*Margaropus annulatus australis*) when they first appeared in that region 20 years ago amounted to 60 per cent. At present the progeny of those cattle in this badly infested territory have acquired an immunity towards diseases transmissible by ticks, but the losses caused by tick irrita-

tion are not generally realised, and are said to amount to 80 per cent. of the total female cattle branded each year. Although present conditions preclude the idea of eradicating the ticks the author suggests that in view of the loss of condition now caused, the suppression by means of systematic dipping must be regarded as the best possible investment for the cattle owner.

The frequency of dipping must depend on the nature of the country. In certain parts it was found necessary to dip every three weeks throughout the year, while in other areas an occasional dipping suffices. It has often been stated that weak cattle and fattening bullocks should not be dipped but the author's experience indicated that in both cases dipping resulted in improved condition; it was found advisable not to put cattle on the road for at least five days after treatment."

—*Trop. Vet. Bull.*

#### Lanark Farmers and Sheep Diseases.

At a meeting of farmers and others interested in sheep, held in the auction ring, Lanark, at the close of the lamb sale on Tuesday, 13th inst., to hear an address by Prof. Gaiger, Glasgow Veterinary College, on the proposed investigations of sheep diseases, Councillor W. K. Jackson, Symington, who presided, strongly commended the work undertaken. He considered there was great necessity for it, and hoped all interested in sheep would give every assistance they could to make the investigation a success.

Prof. Gaiger explained how the College was preparing to begin investigation on sheep diseases, more particularly those of braxy, louping ill, and trembling. The loss from these, he said, was enormous. They were fitting up a complete bacteriological laboratory in the College for the study of animal diseases. The Government and other Boards had given grants in aid, and the Governors of the College were particularly anxious that the work should not be handicapped for lack of the best equipment. They, therefore, appealed to all farmers and others interested for financial assistance to make the investigations a success.

A Committee representative of the different districts of Lanarkshire was appointed to collect subscriptions, and also arrange to provide the necessary material on which to investigate.—*North British Agriculturist.*

## CONTAGIOUS DISEASES AND THEIR CONTROL.

Perhaps some members have not yet realised how much we shall have to do in controlling scheduled diseases in the coming years. Some of the diseases are already scheduled; others are likely to be as soon as other conditions allow the necessary control. Some are now prevalent in this country; and others, from which we are free at present, may be re-introduced.

Our experience of foot-and-mouth disease has taught us what to expect whenever that affection prevails upon the Continent, and it is likely to do so in the near future. A less widely known and very different disease which may cause us some trouble is epizootic lymphangitis. This condition, though common in some French colonies, was little known in France itself; since hostilities commenced it has assumed disquieting proportions in France, but has happily made little headway among the horses of the British Expeditionary Force. Our only experience of epizootic lymphangitis in England was the appearance of a few cases here as a legacy of the South African war. It was scheduled at that time, and quickly stamped out; and there is no doubt that the same measures will enable us to subdue it again, even if a greater quantity of it should be imported.

Rinderpest, though at present more remote, is a far more serious danger. It seems quite possible that the war might be followed by an incursion of rinderpest from Eastern Europe across the western parts of the Continent, and the German penetration far eastward, and the present Russian disorganization tend to render such an event more probable. If it does reach us, we shall be able to stamp it out as we did decades ago; but to do so would tax all our resources for a time.

Even if we import no foreign diseases, our hands will be sufficiently full with those we have here already. Some temporary increase in glanders is practically certain; and equine mange is likely to be very troublesome for some time. The Tuberculosis Order will certainly be re-introduced, perhaps in a stronger form which will enable more cases to be dealt with; and it is not improbable that other diseases not yet scheduled will be as soon as practicable.

Two, at least, ought to be scheduled—epizootic abortion and John's disease. Both are very largely disseminated by the sale of infected animals, which in many cases is done knowingly. Scheduling, with suitable regulations, would check this, and so would effect no small good. Scheduling would also give the Board that accurate knowledge of the local distribution of the disease which can only be obtained

by compulsory notification. Both these diseases might well have been scheduled some years ago; and no excuse could be offered for delaying to schedule them when we have men available for the necessary control. Neither is likely to be subdued quickly or easily; and that is an additional argument for putting them under control as soon as possible.

At present, we are treating many cases of unscheduled disease of all kinds to which we should never have been called in pre-war days. That will probably continue for a long time, and in addition we shall have far more work in connection with scheduled disease than we have ever had before. A greatly increased and progressively expanding activity in the repression of contagious disease will be one of the most striking features in veterinary life for the next generation. One cause of this will be the growing public attention to preventive medicine.

## DETACHED BONY GROWTH IN A HORSE.

I was very interested in an account of an operation on a detached bony growth in a mare by Mr. J. G. Reynard, M.R.C.V.S., which appears in *The Veterinary Record* of the 25th May, 1918. In connection with this, I would like to record the following case:—

*Subject.* A bay light draught horse, admitted to hospital with a shrapnel wound about eight inches above the base of the tail.

The horse was cast with the intention of extracting the shrapnel. The wound was probed and the sinus found to run downwards and outwards for about ten inches.

On manipulating the region of the thigh about four inches in front of the middle part of the femur, a hard, flat, detached substance, which was freely moveable, could be detected immediately under the skin. We at once concluded that it was a piece of bone detached by the shrapnel, and decided to make an exploratory incision.

On cutting down to it, and starting to dissect it out, we found it was a flat, bony plate about eight or nine inches long, and three to four inches wide. It was firmly adherent, and continuous with the fascia in that part. It had nothing whatever to do with the wound, and in my opinion was simply an ossification of the fascia. As it did not appear to be doing the horse any harm, we decided not to remove it, but to leave it in (we had only dissected the top part of it away from the other tissues).

I regret that I cannot say what was the after-result of this case, as I lost sight of the horse.

It is possible that Mr. Reynard's case might have been of the same nature as the one I have here described, and nothing to do with the old wound he describes, or with the piece of shrapnel.

I would like to know if his case caused any lameness or deformity; apparently it did not do so in my case (it was not detected until the horse was cast for operation).

C. H. G. TOWNSEND, Capt. A.V.C.

*Note by Director of Veterinary Services, B.E.F.:*—

"A similar condition was once witnessed by me in an Australian horse in India."

### HYSTERIA (?) IN A MARE.

The subject was a charger, a brown pony mare with a two-month's old foal at foot, and the history was that whilst eating, and about half way through a feed, she apparently became quite mad and was for periods uncontrollable. The mare was noticed to have been in oestrus about three or four weeks previously.

The condition was characterised by localised anaesthesia, sensory disturbance, tonic spasm of one group of muscles and convulsions.

The mare stood with legs apart, with her head and neck held slightly towards the right side, nose pointing towards the chest, and held in a rigid attitude.

Suddenly there would be a convulsion during which she jumped or bucked forwards and towards the left, at the cessation of which she maintained her former attitude. Periods of excitement alternated with those of quietude at regular intervals, the convulsive stage occupying about thirty seconds, whilst the period of torpor was two or three minutes.

In both stages the head was maintained in the position described, and the breathing was stertorous throughout. The pulse was regular, slightly accelerated, full and hard. The muscles of the left neck, jaw, and throat were hard, tense, and in a condition of tonic spasm, whilst the skin over this area was anaesthetic. The left eye was open and staring with the pupil dilated, and loss of vision. The skin on the right neck was sensitive, whilst the eye and eyelids on the right side were capable of movement, and the sight was unimpaired.

Arecoline gr.  $\frac{3}{4}$  and morphine gr. iii were injected on opposite sides. The arecoline acted in about five minutes and continued for half an hour. During this time the animal defaecated three times and micturated once; a considerable quantity of urine being passed.

From that stage at which salivation commenced there was improvement. A gradual relaxation of the tetanised muscles was noticed, the stertorous breathing disappeared, the left eyelids flickered, the head assumed a more normal appearance and its carriage was better. The mare stood in a more

easy and natural position, and her movements were more co-ordinated. Recovery occurred in three-quarters of an hour.

In attempting to arrive at a diagnosis of this case, the only conclusion I could arrive at was that it might be hysteria. In the early stages I suspected some congestive or inflammatory condition of the brain or meninges, but the symptoms were so transient, recovery so rapid, and the nervous phenomena so varied that I concluded they were unassociated with any organic disease. The fact that the affection occurred three or four weeks after the oestral period, and at a time when its recurrence might be looked for lent weight to this view.

Cases of this nature are apparently uncommon, I have therefore deemed it worthy of record.

R. P. JONES, Capt. S.A.V.C.

### ABSTRACTS FROM FOREIGN JOURNALS.

#### GLANDULAR TUBERCULOSIS WITH ABSCESS FORMATION IN THE OX.

Demé records the following case on account of the rare localisation of the lesions and the dimensions they acquired. This mode of degeneration, according to Nocard and Leclainche, is frequent in the superficial glands. It is also observed in the visceral glands, especially in the posterior mediastinals. In Demé's case, the glands involved were intermuscular—the popliteal and prescapular.

The subject was an ox, four years old. The animal presented a greasiness in the region of the right hip and fluctuation of the superficial part of the thigh. A blister was applied to this point; and some days later an incision released four litres of pus. Despite repeated antiseptic applications, the suppuration could not be arrested. In addition, three months afterwards a swelling was seen in the anterior region of the right shoulder. This decided the owner to send the ox to the slaughter-house.

*Post-mortem.* Caseo-purulent centres were found in the liver, with concomitant alterations of the annexed glands. No particular lesion was found in the mesenteric, bronchial, and retro-pharyngeal glands. The examination of the other deep glands was more fruitful. The right popliteal gland had attained the size of a man's head. On section it appeared crammed with rounded tubercles the size of nuts, in contact with a caseo-purulent liquid. The pus had extended through the subcutaneous connective tissue and the neighbouring intermuscular spaces. The skin was detached over a space the width of two hands.

The right prescapular gland had doubled its volume. It was surrounded by a thick and very resistant fibrous coat. Upon section it presented tubercles identical with those of the popliteal, immersed in pus. Here the suppuration had remained circumscribed.

The majority of the remaining glands showed hæmorrhagic lesions.

Probably the tuberculosis was of intestinal origin.

The liver, attacked early, rapidly became the seat of caseo-purulent centres, this may be attributed to an excessive virulence of the specific bacilli. Generalisation through the blood stream followed.

The carcase was totally condemned.—(*Revista de Higiene y Sanidad Veterinaria*).

### SPECIAL TRIBUNAL.

#### REGISTERED VETERINARY SURGEONS.

In pursuance of the provisions of Regulation 54 of the Military Service Regulations, 1918, the Local Government Board and the Secretary for Scotland hereby appoint:—

F. W. Garnett, Esq., C.B.E., M.R.C.V.S.  
G. A. Banham, Esq., F.R.C.V.C.  
Hugh Begg, Esq., F.R.C.V.S.  
O. Charnock Bradley, Esq., M.D., D.Sc., CH.B., M.R.C.V.S.  
J. Clarkson, Esq., M.R.C.V.S.  
H. J. Dawes, Esq., F.R.C.V.S.  
Sir John M'Fadyean, LL.D., M.B., C.M., B.Sc., M.R.C.V.S.  
W. J. Mulvey, Esq., F.R.C.V.S.  
S. H. Slocock, Esq., F.R.C.V.S.  
J. Willett, Esq., M.R.C.V.S.  
P. Wilson, Esq., M.R.C.V.S.  
W. Woods, Esq., F.R.C.V.S.

to be a special Tribunal (hereinafter called the Veterinary Tribunal) for the purpose of dealing, on and after the twenty-eighth day of August, 1918, with any application, or request for leave to make an application, for the grant, renewal, variation or withdrawal of a certificate of exemption to, or held by, any man (not being a duly qualified medical practitioner) who is a duly qualified veterinary surgeon registered under the Veterinary Surgeons Act, 1881. F. W. Garnett, Esq., C.B.E., M.R.C.V.S., is hereby appointed to be Chairman of the Veterinary Tribunal.

And the Local Government Board and the Secretary for Scotland direct that the powers, functions and procedure of the Veterinary Tribunal in relation to the matters aforesaid shall be the same as those of an Appeal Tribunal when dealing with applications, or requests for leave to make applications, made direct to them under the Military Service Regulations, 1918, as amended by subsequent Regulations.

Dated this twenty-first day of August, 1918.

W. HAYES FISHER,  
President of the Local Govt. Bd.

ROBERT MUNRO,  
His Majesty's Sec. for Scotland.

An Official Circular issued to Tribunals states:—

"It has been decided that no registered veterinary surgeon shall be taken for military service except, if he is suitable, as a commissioned officer for employment in his professional capacity, subject to the condition that, if a veterinary surgeon is left in civilian employment, he is engaged on such veterinary work as is deemed to be most in the national interests.

"In this respect the position of registered veterinary surgeons is similar to that of registered medical practitioners and registered dentists, and it is important to secure the best distribution of their services."

The address of the Veterinary Tribunal is 10 Red Lion Square, London, W.C.1.

### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

D. A. D. Aitchison, Madras	£1 1 0
S. J. Motton, Capt. A.V.C.	1 1 0
R. G. Saunders, Penzance	1 1 0
John S. Wheatcroft, Rotherham	1 1 0
Previously acknowledged	966 9 11
	£970 13 11

## PARLIAMENTARY.

## TUBERCULIN TEST.

Mr. WRIGHT asked the President of the Local Government Board whether there are now, or if he intends to impose, any restrictions on the possession and use of tuberculin by persons other than members of the Royal College of Veterinary Surgeons, in view of the fact that previous injection of tuberculin within six weeks renders the tuberculin test worthless.

Mr. FISHER: I am not aware of any restrictions at present. I am consulting the Board of Agriculture and Fisheries in regard to the question whether any restrictions should be imposed.

Mr. WRIGHT: Will my right hon. friend say how he proposes to ensure that the consumers, who, under the new grading of milk scheme, pay 3d. or 4d. a gallon extra for Grade A or Grade B, get what they pay for, in the absence of any such restrictions?

Mr. WRIGHT asked the President of the Local Government Board whether he can give any information as to number and ownership of dairy herds which contain no animal which reacts to the tuberculin test.

Mr. FISHER: I have not at present any information on the subject.

## Swine Fever Prosecution.

At the Chelmsford Sessions on Friday, Geoffrey Matthews, Good Easter, was summoned for exposing in the Chelmsford Market, on August 2nd, pigs suspected of swine fever, and also for not giving notice that pigs in his possession were suspected of swine fever. Ralph Matthews, his brother, was summoned for moving, between July 10th and August 10th, at Good Easter, swine into a swine fever infected area without a licence. Both defendants are well-known farmers.

Mr. W. S. Mulvey, veterinary surgeon, Chelmsford, said that on August 2nd he saw 39 store pigs in the market, most of them in a poor condition. Suspecting swine fever, he had them removed, and two days later he slaughtered two, and found them affected. They must have had the disease when they were sent to the market.

Supt. Mules said that Mr. Geoffrey Matthews admitted that the 39 pigs were his, and that they were in a poor condition, but he said he was perfectly sure at the time they were not suffering from swine fever. He attributed their condition to the difficulty in obtaining proper food, and also that he was afraid the attendant had neglected his duty in feeding them. Defendant also told witness that his three sons were in the army, as well as some of his best workmen, and that he could not attend to all the necessary details on the farm.

Mr. D. A. Cragie, Board of Agriculture Inspector, said that any man with experience should have had strong reasons for suspecting disease in these pigs.

Mr. Geoffrey Matthews said there were no signs of disease when the pigs left the farm. The food he had given them was what was advised by the Board of Agriculture, but he was inclined to think it was too strong.

The Mayor (Mr. J. Gowers) said the Justices were unanimously of opinion that Mr. Geoffrey Matthews did not suspect swine fever, and they dismissed the cases against him.

With regard to Mr. R. Matthews, Supt. H. Mules explained that the defendant moved some pigs from one of his farms to another which was an infected area at the time.

Mr. Matthews said that originally all the pigs belonged to one lot; those he moved had been treated by the Board's Inspector, and declared immune from disease. He could have sent them to market, but he put them with the others, intending to keep the lot on his farm until they were killed.

A fine of £2 was imposed, the Justices thinking that this would not have happened had Mr. Matthews read the notice served upon him.—*East Anglian Daily Times*.

## Alleged Cruelty at Brighton.

## WARTS ON A HORSE.—DISMISSED.

At Brighton Borough Bench, on Thursday, 22nd inst., Joseph Nye, of St. James's Mews, was defendant in an adjourned summons for ill-treating a horse by working it in an unfit condition.

The Magistrates on the Bench were Mr. Wallis (in the chair), and Mr. Saunders.

Mr. T. Digby Gates prosecuted on behalf of the Royal Society for the prevention of Cruelty to Animals, and defendant, who pleaded not guilty, was represented by Mr. Doughty, barrister, instructed by Mr. J. C. Buckwell.

P.C. Miller said: On 25th July he was on point duty in Old Steine, when he saw defendant driving a brown gelding attached to a gig. As it passed, witness noticed a number of warts between the hind legs. Two were raw and red, and witness decided to stop defendant when he returned. He did this at 11.30, and then examined the horse. Seeing Inspector Whiting passing by, witness called him, and it was agreed that defendant should drive on to his yard. On arriving there witness found the two warts that he had noticed had been covered over with some black substance. There was also a large wound about the size of a man's hand on the flank. Two other warts that were not bleeding were about half the size of a man's fist; the two that were rubbing together and from which blood was dropping, were about the size of a chicken's and a pigeon's egg respectively. There was blood on both hocks from these warts.

Replying to Mr. Gates, witness said the black substance which he noticed on the warts had been put on them after witness stopped defendant.

Cross-examined, witness said he had previously noticed the horse had warts, but on this occasion they looked red, and so he stopped defendant. Witness was quite convinced it was blood that was coming from the warts. The animal was a spirited one and very fast. There was no trace of lameness and its action was perfectly free both before and behind. The horse showed no signs of nervousness. Witness adhered to his statement that he saw the warts rubbing together, though Mr. Doughty suggested that this was physically impossible.

Inspector Whiting, R.S.P.C.A., testified that the horse was in good bodily condition, but said two of the warts on the hind legs were bleeding. He spoke of an examination by three veterinary surgeons at defendant's yard. In cross-examination, he said the animal was a showy one, with a free action, and there was no sign of distress or pain, although it was rather nervous when examined. He agreed that defendant owned a good many animals, and had always given him every assistance when he had had occasion to go to his yard. If the warts did not rub there would be no cruelty in working the horse. He agreed that the warts without being rubbed, would break down from time to time, and show raw. The fact that the warts looked raw would be no proof that they were rubbing. He knew Mr. Pritchard maintained that the warts did not rub, and agreed that they did not touch when the animal was standing still. Witness advised Mr. Nye not to work the horse, and he had followed the advice.

Mr. Richard Burt, M.R.C.V.S., said he formed the opinion that there was friction between the two warts and that it was cruelty to work the horse while in that state. Mr. Pritchard did not agree that it was cruelty to work the animal.

Cross-examined, witness agreed that if there was no friction between the warts there would be no cruelty.

The warts might appear raw although there had been no friction. It was a handsome animal, and except for this defect a valuable one—worth 100 guineas or more. Witness considered that while the animal was in the condition in which he saw it it should never be taken out of the stable.

By the Bench: Warts were not painful in the ordinary way, except when there was friction.

Mr. W. K. Stuart, M.R.C.V.S., 2 Osborne Villas, Hove, said one of the two warts that were bleeding did not touch on a straight course, but did so in turning. Witness was emphatically of opinion that it was cruelty to work the horse, and was of opinion also that a wound remaining where a wart had been removed by operation would also be painful. In cross-examination, he said that when the warts were on the point of breaking the smallest touch would make them appear raw.

#### THE DEFENCE.

Mr. Doughty suggested that the only points at issue were whether the warts were touching, and whether the horse was driven so as to cause it unnecessary pain. If the Magistrates found that Mr. Nye was driving the horse about for a substantial period of time indifferent as to whether the warts were touching or no he would not resist a conviction, for he thought it would be cruelty. He would, however, ask the Bench to hold that, in fact, the warts were not touching; that the horse had an extremely wide action; and that as the legs crossed the warts in no way touched unless that happened when it turned.

The Court adjourned for luncheon, and during the interval the horse was examined by the Magistrates.

On the resumption, defendant, giving evidence on oath, said he was a jobmaster and livery-stable keeper, in business on his own account for 25 years. He took the horse over from Mr. Allen, who formerly traded as Dupont. It was the subject of warts, and bore marks of having been operated upon. Witness had never let the animal out, and simply used it for his own purposes—very light work. He had attempted to cure the horse of the warts, and it had been constantly under the care of his veterinary surgeon. The warts were all removed in March, 1917; others grew, and were removed in November the same year. In June of this year he noticed the warts were growing again, and mentioned the matter to Mr. Pritchard with a view to another operation. From that time he took the animal out about four times a week, merely in order to drive from one of his yards to another. When witness first saw the horse on the 25th July, the warts were dry and not exuding at all, but when driving down St. James' Street shortly after eleven, he noticed a moisture. Since that date the animal had not been driven out, and the warts were much worse now. The horse was a favourite, and would follow him about. It was a spirited animal, and if the warts rubbed as suggested it would have kicked.

Cross-examined: He denied that there was any blood dropping from the warts on to the hocks, but there was a fluid inside the thighs from them. Witness had never seen the warts touch, even when turning. He denied that the animal had received any treatment since 25th July for the warts beyond cold sponging. He admitted that between the time when he was stopped in Old Steyne and the time when the examination was made at the yard he dabbed the warts with some substance. He thought that was a mistake, and was sorry for it. If the warts touched, witness agreed that it would not be right to work the horse; neither would it be safe.

Mr. Pritchard, M.R.C.V.S., County Council Inspector for the Arundel and Chichester divisions of West Sussex, said he was first consulted about the horse in July, 1916. The animal was the subject of warty, fibrous skin growths in both groins. In March, 1917, he removed 11 such growths. The growths were in the inner layer of

the skin, and as they grew, they ruptured the outer skin, breaking it down. Witness declared that the operation would not be painful unless touched or rubbed. In June last Mr. Nye drew his attention to the warts, which were growing again, and witness advised him that the horse could quite well be worked, but asked him to let him know how it got on. As the result of a thorough test on 25th July, witness was satisfied that the warts did not touch, nor did they do so now, and so long as they did not touch there was no pain and no cruelty. What was alleged to have been blood dropping on to the legs was not blood but an exudation.

Cross-examined, witness considered the animal quite fit to be driven at the present moment. In turning, the warts might touch, but would not drag, and the pressure would not be sufficient to cause chafing.

Mr. J. C. Munby, of Lewes, Veterinary Surgeon and Inspector for the County Council, also gave evidence as to the condition of the horse, and described some tests he made, proving that the warts did not touch.

Cross examined: Occasional friction of the warts would not cause pain. The animal was quite fit to be worked at the present time.

Mr. Jas. Edward Wallis, M.R.C.V.S., Hailsham, County Council Divisional Inspector, who examined the horse on the 27th July, said he actively manipulated the warts, but no signs of sensibility were to be noticed, and the animal also showed no signs of pain or discomfort.

Cross-examined: Witness thought the animal was fit to work, but a lot of turning would not do it much good.

After a lengthy consultation, the Chairman observed that there was a great conflict of evidence in the case, particularly in the evidence of the five veterinary surgeons—such a conflict as to raise doubts in the minds of the Magistrates, of which defendant must, of course, have the benefit. The case would, therefore, be dismissed.—*Sussex Daily News*.

#### STERILISED TUBERCULOUS MEAT.

*The Editor "Meat Trades' Journal."*

Sir,—I am glad to notice from Scotus' letter in your issue of this date that the Glasgow meat trade intend to sterilise this pet scheme of Mr. Trotter's. The proposal is an absurd one, seeing that it would add an infinitesimal and unsatisfactory addition to the food supply. It would turn the public in this country off beef. It might do for the population of Germany, who are cultured up to swallow almost anything. It took some years to get meat producing countries into line on the question of the issue of inspection certificates. What will they think of us if we go back on our former practice. The meat producing States would be justified in withdrawing their certificates of inspection and send, as before, uncertified packages of meat. Everybody knows that the inspection of meat is now conducted on rational lines in almost all centres, and that what is condemned ought not to be sold for human food in any shape or form. A large number of most capable veterinary surgeons are serving in the army. They would, I am sure, condemn the proposal. I trust that Bailie Roderick Scott will succeed, with the help of the meat trade, in putting a stop to the mischievous fad of a few—a very few—members of the veterinary profession.

Aug. 15.

Yours, etc., MERKLANDS.

The foregoing needs little explanation. Most of your readers will have seen references to the subject in the local or agricultural papers during the last few weeks. I have seen other letters in which Mr. Trotter is stated to have entirely changed his views on the matter. I believe that for some years Mr. Trotter has held that

tuberculous meat is unfit for human food, and has shaped his inspection in accordance with that opinion: but I fail to see that because he has expressed himself in favour of sterilizing tuberculous meat for human food, he has therefore gone back on his previous opinions.

It seems to me that several of the men who have written against the procedure are ignorant of the significance of the word sterilize. They don't know that when their Sunday joint is *cooked through* in their own oven it is sterilized. The process is the same but more efficiently carried out in the specially constructed sterilizing chamber.

So far as I know, no one has suggested that flesh which is badly infected with tuberculosis should be dealt with, nor that the process will render such flesh fit for food. But cattle in good condition as to flesh, are sometimes found with badly infected organs; in given conditions much of this flesh can be made safe for food—and there is sufficient evidence that the food so prepared is palatable and contains a good amount of nourishing elements. A substance or fluid is “sterilized” when it has been submitted to such heat that organic life has ceased to exist in it—thus, all living infection is destroyed, and food so prepared cannot be termed injurious, while its nutritive value depends—not upon the process, but upon the quality of the flesh before it is treated.

The risks attached to the installation of a plant are—from the financial side, the question of supply of material for treatment. From the Public Health side the efficient selection of suitable material: and capable management of the apparatus. But, that at a time of scarcity of food, such as will have to be faced for some time to come, men should be allowed to obstruct such a scheme on sentimental grounds alone does not speak well for our intelligence as a nation.

I have nothing to gain or lose on the question—I am not a meat inspector, nor a butcher, nor an engineer with appliances to sell. I am inclined to approach the subject as a consumer—and in that connection I ask myself, Is this sterilized meat likely to be any worse than the “lamb” which has been cold-stored until it is utterly flavourless, and it crumbles instead of cutting under the carving knife, and the fat is tallow? Or is it worse than the mutton which is difficult to cut, and impossible to chew? Or than the beef which has to be stewed twice, and is almost reduced to stock, before it is eatable?

Looking through a paper and discussion on “Meat inspection in rural districts” in *Journal of the Sanitary Institute*, and with a recollection of having read somewhat similar experiences in your pages, Mr. Editor, I was forced to the conclusion that a good many of those concerned in the supply of flesh food in this country—farmers, butchers, and meat salesmen—shirk all responsibility in the quality of the food they supply. Possibly some of your readers may appreciate the following extract from the paper by Dr. W. G. Savage, County M.O.H. Somerset.—Yours, etc.,

SENEX.

“There exists a slaughter-house, situated in the country but at a convenient distance from a railway junction, in connection with which I received definite and specific complaints as to traffic in diseased meat, where the meat went, and even how it was sent. On investigation I found that the slaughter-house was a licensed one, and that the occupier was allowed to use it both as a knackers' slaughter-house and for the slaughter of food for man: a unique opportunity. At my first visit (a surprise one) I found an emaciated tuberculous cow being cut up. The occupier of the premises, with the most engaging frankness, admitted that it was unfit for food, and assured me that no one

had any intention of so using it, and in *proof* thereof he went to the house and produced address labels to a cats' meat man in London, to whom he had intended to consign the meat. There were two other animals waiting to be killed, one being emaciated and probably diseased.

The premises were defective structurally, and I saw to it that the owner was compelled to reconstruct, while of course I insisted that the premises could be licensed for one purpose only. The reconstruction was carried out at very considerable expense, and the premises are now licensed as a knackers' yard; but one is still left wondering at the profitability of the knackers' trade to make the heavy cost worth while.

Another case is even more interesting. Some years ago extensive premises were constructed as a slaughter-house in the heart of the country, but adjacent to a small railway junction. The sanitary inspector of the district lives five miles away. The premises are situated several hundred yards from the road, so that the approach of any inspector or other visitor can readily be seen, while admittance to the actual premises is through a gate which I have always found locked. The slaughtering premises are quite extensive, and structurally very satisfactory and up to date. In the very middle of the premises is a room, again structurally satisfactory, in which sausages were prepared on a large scale. The licensee has been fined once to my knowledge before coming to Somerset for selling diseased meat, while he successfully objected before the rural district council to give an undertaking not to kill meat for both human food and animal food. Any diseased meat found on his premises could therefore without difficulty be designated as animal food. A local newspaper describing the opening of the premises stated, but in quite another connection, ‘The spot is an ideal one for such a business.’

The premises are now unoccupied, as a large batch of diseased meat seized in London was traced back to this place, and the occupier absconded. Meanwhile, I had very considerable difficulty in making clear to the rural district council that there must be a definite undertaking that the premises should be used for one kind of slaughtering only.

One other case. In one of the rural districts, a slaughter-house was licensed, although of rather poor construction. The occupier was known to have been fined, before he came into the county, for dealing in diseased meat, and there were strong reasons for believing, but not sufficient for definite proof, that his accomplishments in this direction, acquired in another county, were not being neglected in ours. The medical officer of health was energetic and keen, and, although no conviction was obtained, things were made uncomfortable, and the occupier migrated to another part of the county. He now occupies premises on the border between two rural districts, and equally inconvenient of access for both inspectors, but with a railway station conveniently adjacent. He has added to his establishment a large dog, with accomplishments not inferior to those of his master; for the advent of any stranger into the lane leading to the slaughter-house at once produces the brute, who blocks the way and growls, conveying the unmistakable impression that long familiarity with meat has blunted his powers of discriminating between the tearing of human and of animal flesh, and a little absence of discretion in advancing will inevitably break down his forbearance. Naturally, you forbear to increase the feeling of tension, and after an interval varying with the needs of the case, the owner appears, and smilingly invites your approval of his premises. I have not been there for several years, so do not know if this description still holds true.

Speaking generally, the slaughter-houses in rural and the small urban areas are fairly satisfactory as regards structure and surroundings, the chief defects being

broken floors, while very few have cement-lined or other form of impervious wells.

As regards their use, a defect, which is much commoner in rural and small urban districts than in large towns, is that in a number of instances they are not kept entirely for their proper purpose. I have, for example, found a load of peat, a mattress, old clothing, bicycles, meat safe with food inside, harness, etc., stored in different slaughter-houses. It is also not very infrequent to find sausage-making and food-pickling conducted in the slaughter-house itself."

### ARMY VETERINARY SERVICE

War Office, Aug. 22.

The King has been pleased to give orders for the following appointments for valuable services rendered in connexion with military operations in German South-West Africa:—

#### ORDER OF THE BRITISH EMPIRE. COMMANDERS (C.B.E.)

\* \* \* \*

Lt.-Col. (Hon. Col.) James Irvine Smith, S.A.V.C.

War Office, Aug. 22.

The King has been pleased to approve of the following rewards for distinguished service in the Field and in connexion with the campaign in German South-West Africa, 1914-15; to date from Jan. 1, 1916:—

#### THE DISTINGUISHED SERVICE ORDER

Maj. J. G. Bush, Maj. G. W. Lee, S.A.V.C.

#### THE MILITARY CROSS.

Capt. P. R. Viljoen, Capt. C. H. Wadlow, S.A.V.C.

War Office, Aug. 22.

The Secretary of State for the Colonies has received from the Governor-General and Commander-in-Chief, Union of South Africa, the following list of officers and other ranks whose names have been brought to notice by General the Rt. Hon. Louis Botha for distinguished service in the field and in connexion with the campaign in German South-West Africa, 1914-15:—

S.A.V.C.—Capt. W. H. Andrews; Maj. J. G. Bush; Capt. F. J. Dunning; Capt. S. Elley; Capt. A. Goodall; Capt. A. M. Howie; Maj. W. Jowett; Maj. G. W. Lee; Capt. D. B. J. McGill; Capt. J. McNeil; Lt.-Col. (and Hon. Col.) J. Irvine Smith.

War Office, Aug. 26

The King has been pleased to approve of the following rewards for distinguished service in connexion with Military Operations in Mesopotamia (Dated June 3, 1918, unless otherwise stated):—

TO BE BREVET MAJOR—(Actg. Maj.) G. Williamson.

#### DISTINGUISHED SERVICE ORDER.

Maj. (actg. Lt.-Col.) A. J. Williams, F.R.C.V.S.

War Office, Aug. 27.

The Secretary of State for War has received the following dispatch:—

General Headquarters,

Mesopotamia Expeditionary Force, April 15, 1918.

Sir,—With reference to the concluding paragraph of my dispatch dated the 15th April, 1918, I have the honour to submit herewith the names of officers serving, or who have served, under my command, whose distinguished and gallant services and devotion to duty I consider deserving of special mention.

I have the honour to be, Sir, your obedient Servant,

W. R. MARSHALL, Lieut.-Gen.,  
Commanding-in-Chief, Mesopotamian  
Expeditionary Force.

Capt. R. M. Bamford; Maj. P. V. Beatty; Temp. Capt. T. Childs; Temp. Capt. R. W. D. C. Easom; Temp. Capt. J. Forbes; Temp. Capt. J. R. Hewer; Maj. J. Nicholas; Maj. (actg. Lt.-Col.) A. J. Williams, F.R.C.V.S.; Capt. (actg. Maj.) G. Williamson; Temp. Capt. N. Wright.

Extracts from *London Gazette*.

WAR OFFICE, WHITEHALL, Aug. 22.

#### REGULAR FORCES. ARMY VETERINARY CORPS.

To be temp. Lts.:—D. P. White, B. S. Parkin, T. J. Hurley, J. A. McCutcheon (Aug. 7); J. T. Alcock (Aug. 8).

Aug. 23.

Temp. Lts. to be temp. Capts.:—C. S. Northcott (Aug. 6); R. E. Bond, J. W. Knowles, K. A. Miles, F. C. Scott (Aug. 8).

Aug. 24.

To be actg. Lt.-Cols. while comdg. Vety Hosps.:—Maj. E. C. Webb, O.B.E., F.R.C.V.S.; Maj. H. E. Gibbs, D.S.O.; Maj. H. T. Ryan, D.S.O., F.R.C.V.S.; Maj. A. Leaning, D.S.O.; Maj. F. C. O'Rorke, C.M.G., F.R.C.V.S.; Maj. H. Kirby, D.S.O.; Maj. (Bt. Lt.-Col.) T. E. Burridge; Maj. K. McL. McKenzie, D.S.O.; Maj. J. S. Nimmo, D.S.O.; Capt. (temp. Maj.) J. R. Hodgkins, D.S.O., F.R.C.V.S.; Capt. (temp. Maj.) W. H. Walker, D.S.O.; Capt. (temp. Maj.) J. O. Andrews, D.S.O.; Capt. (temp. Maj.) V. C. Leckie, D.S.O.; Capt. (temp. Maj.) A. Hodgins, D.S.O. (June 15).

Aug. 26.

To be temp. Lt.:—J. M. Walker, F.R.C.V.S. (Aug. 9).

Aug. 27.

Temp. Capt. J. McBirney resigns his commn. (Aug. 28).

Temp. Lts. to be temp. Capts.:—E. A. Pearce, E. P. Shallcross (Aug. 13); P. W. Bloye, L. P. Pugh, T. J. Lewis (Aug. 14).

To be temp. Lt.:—J. Knox Irvine (Aug. 12).

Temp. Qrmr. and Lt. E. H. Morton is dismissed the service by sentence of a Gen. Court-Martial (July 8).

#### TERRITORIAL FORCE, ARMY VETERINARY CORPS.

Aug. 23.

Capt. J. S. Bowden to be actg. Maj. while empld. as D.A.D.V.S. (Mar. 13).

Aug. 24.

Capt. (temp. Maj.) T. D. Young, O.B.E., to be actg. Lt. Col. while comdg. a Vety Hosp. (June 15) (substituted for that which appeared in *Gazette* Aug. 9).

CANADIAN A.V.C.

Aug. 22.

To be temp. Capt.:—Spr. W. C. Batty, 2204332 Aug. 6).

The following casualty is reported:—

WOUNDED—Capt. L. E. L. Taylor, Can. A.V.C.

#### Personal.

Dr. CLEMENT STEPHENSON, veterinary surgeon, Newcastle, has bequeathed £29,000 to public objects, including £5000 to the Royal Veterinary College, London, to found a Clement Stephenson Scholarship, £5000 to the Victoria Veterinary Benevolent Institution, London, to provide gratuities or annuities for deserving widows and families of veterinary surgeons, and £5000 to Armstrong College, Newcastle.

Mr. C. C. NESLING, M.R.C.V.S., of Framlingham, was riding his young chestnut mare on Monday, and had stopped near a field at Coles Green, in which a steam plough was operating, in order to accustom it to the noise of the plough, when it became restive and appeared to lose control of its hind-quarters, causing the rider to slip from its back, and in the kicking and plunging which followed, Mr. Nesling sustained a compound frac-

ture of the left leg. He is reported progressing as well as can be expected.

**FRASER—CLARKE.** On the 17th Aug., at Caterham Congregational Church, by the Rev. Arthur Pringle, assisted by the Rev. W. C. Bourne, Maj. Angus Russell Fraser, M.G.C., youngest son of the late James Fraser, F.R.C.V.S., of St. Albans, and Mrs. Fraser, of Letchworth, to Ida May, youngest daughter of the late James G. Clarke, M.A., J.P., of Caterham, and Mrs. Clarke, of Felixstowe, and Witlesham Hall, Suffolk.

**STEEVENSON—QUIGGIN.** On 24th Aug., at St. Peter's, Formby, by the Rev. Canon M. Linton Smith, D.D., D.S.O., Rector of Winwick, assisted by the Rev. J. Brook Richardson, M.A., Vicar of Holy Trinity, Formby, Maj. J. R. Steevenson, D.S.O., son of the late R. H. Steevenson and Mrs. Steevenson, of Torrington, Devon, to Muriel Theodora, elder daughter of Mr. and Mrs. D. A. Quiggin, of Tower House, Freshfield, Lancs.

At the annual show of the Fettercairn Farmers' Club the display of draught horses was the feature of the day's exhibition. In an entry of eleven mares, Clydesdales, Prof. Dewar, Balbegno, obtained a first with the five-year-old Finella, by Craigie Dorando, out of the Baron Cedric mare, Nora of Balbegno: and her filly foal worthily won in a strong class.

#### INSURANCE CO. FEES.

Dear Sir,—It has just come to my knowledge that veterinary surgeons of a certain county are willing to examine horses for Insurance Companies at the rate of *sixpence* per mile (one way only charged) extra to the examining fee.

Can it be true? Are they aware that there is a war on, or is the circular a huge joke?

Yours, etc., W. V. S.

#### SUPPLY OF VETERINARY SURGEONS FOR THE ARMY.

Sir,—I read with much interest the details of the above in my *Record* of the 24th inst.

I am afraid I must disagree with the two main assertions of our President, *viz.*, (1) "that during the last four years the Council of the R.C.V.S. has used every means in its power to endeavour to secure the services of as many qualified men as possible with the A.V.S." (2) "the still urgent need for qualified V.O. fit for service overseas." I know of a fully qualified veterinary surgeon, unmarried, aged 34, who has studied for the degree of D.V.H., and who is now serving as a private in the R.A.M.C.

He has been employed *overseas* in the capacity of a private in the R.A.M.C. He is now employed in an office engaged in keeping the medical or surgical history sheets of patients passed into and out of the hospital, and his position is what I term "a dignified ward clerk."

His name is on the Register R.C.V.S.

Some considerable time ago he applied to his C.O. for the C.O.'s sanction for him (the V.S.) to apply for his commission in the A.V.S. He is still a private in the R.A.M.C.

If the President of the R.C.V.S. or the D.G. of A.V.S. desire proof of all that I have stated, I should in strict confidence be pleased to transmit the fullest particulars.

"JOSEPH BINDLE."

Aged 38, married, and passed Class A; and ready to answer the call when the Tribunal desires my presence.

I enclose my name and address.

#### VETERINARY SURGEONS AND IRISH CONSCRIPTION.

When the Government stops playing the fool and applies conscription to Ireland, the above department ought to have a fine capture. The South of Ireland is full of them.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1574

SEPTEMBER 7, 1918.

VOL. XXXI.

## VETERINARY FEES.

To-day we print details of an arrangement which is being satisfactorily worked by some practitioners of Derbyshire and Staffordshire, and which deserves consideration by the professional associations and by groups of neighbouring colleagues. The scale of fees given may require alteration to suit the conditions of different districts; and the first advantage of the arrangement is that, being purely local, the minimum fee may not be the weak point it must be in any scale of fees for application throughout the country. Probably it is upon such lines that the question of fees will be most effectively adjusted—by local arrangements amongst neighbouring practitioners, which professional societies might do a great deal to bring about. Another admirable, indeed the essential, point in the plan is that the combined action appears to be complete; and here again the localisation of the method is advantageous. Veterinary Surgeons are not much accustomed to act in combination in these matters; and there are districts in which it will be difficult to attain unity, but there are many others in which it can be effected. In any case, a local combination should be more easily established and more satisfactorily worked than a national one. These colleagues in the Midlands deserve thanks for acquainting the profession with their doings.

## VOLUNTARY SUBSCRIPTIONS.

In 1917, the total voluntary subscriptions received during the year amounted to £960. This year we are doing decidedly better. Last year's figure of £960 was passed during last month; and at the end of the month the published total just exceeded £970. We can thus hope for a substantial increase on last year's total when this year ends; and those who follow the College finances well know the need for it.

Last year, despite the subscription of £960, there was an adverse balance of some £250 at the end of the year, due to the increased loss upon examinations. Had it not been for voluntary subscriptions, the College would have lost £1200 on the year. As it was, the loss was serious enough; but the subscriptions prevented it from assuming ruinous proportions.

This year the losses upon examinations will probably exceed those of 1917; and we may be fairly certain that £1200 will not avert some loss at the end of the year. Some such sum would at least prevent any very serious deficit. To have exceeded last year's total and approached £1000 in the first two-thirds of this year is a good start; but more

ought to be done. Very many members have not yet subscribed; and their duty is clear.

It will be a long time before our Bill can be re-introduced into Parliament with any hope of success; and in the meantime only voluntary subscription can save the R.C.V.S. from bankruptcy. Indeed, had it not been for voluntary subscription, bankruptcy would have come before now, as members of Council have recently acknowledged. The Council delayed long before asking for a voluntary subscription, and only did so as a last resource. It will never be an adequate substitute for the Bill; but, such as it is, we must make the best of it. Those who have not yet subscribed should do so; those who have should try to stimulate others.

## HODGKIN'S DISEASE IN THE DOG.

By WM. PAUER, M.R.C.V.S., Blackwater, Hants.

*Subject.* Spaniel bitch, three to four years old.

*History.* She was usually in excellent condition, and had had no previous illness.

*Symptoms.* My attention was requested to her in May of this year, she then had enlarged submaxillary glands; they were hard, and not painful to the touch, and about the size of a pigeon's egg. Her appetite was good, and they did not appear to inconvenience her in any way.

In June, the pharyngeal and prescapular and superficial inguinal glands became similarly affected, and week by week they increased in size until each was about as big as a walnut. The bitch began to lose flesh, and in August became emaciated. The mesenteric glands could then be felt through the abdominal walls as large as a hen's egg. Pneumonia supervened, and she was destroyed.

*Treatment* consisted of daily application of Tinct. iodi. to the glands, and 2 grs. of Pot. iodide internally twice daily.

*P.M.* All the external and internal glands, including the prepectoral, bronchial and mesenteric, presented a similar appearance, being greatly enlarged and firm to the touch, and containing a thick, milky-looking fluid. Liver was apparently in a state of fatty degeneration and lungs showed recent congestion.

*Remarks.* As I had not previously met with this condition, I sent the viscera to the R.V.C. for examination, and Mr. Edwards, B.Sc., M.R.C.V.S., kindly reported that the disease was Hodgkin's Disease, in which there is marked hyperplasia of all the lymphatic tissues of the body, and that the cause of the condition has not hitherto been discovered.

## LAMINITIS—A QUICK RECOVERY.

One evening I was called to a cart mare which had just returned from an eighteen-mile road journey. I found her suffering from acute laminitis of the fore feet. I gave her a 7 dr. physic ball, and a subcutaneous injection containing  $1\frac{1}{2}$  gr. arecoline. I had her shoes removed and her feet placed in cold bran poultices, and left instructions that her feet be well doused with cold water throughout the night. Next morning the mare was almost sound, and made a good recovery.

J. M. WHYTE, M.R.C.V.S.

Tenbury, Sept. 1st.

## ABSTRACTS FROM FOREIGN JOURNALS.

## CATHETERISATION OF THE BLADDER IN THE BITCH.

Gago published an article upon this subject in the *Revista de Medicina Veterinaria* for 1915. He claims to have found a technique for catheterising the bladder of the bitch which is more certain and more easy than the ordinary imperfectly described ones. The materials required are a 1 in 1000 solution of potassium permanganate, a lubricant, a vaginal speculum with movable laminae, and a straight metallic catheter. The bitch is fixed upon her back by the four limbs; and an assistant secures her head. The vagina, vulva, and vulvar lips are washed with the potassium permanganate solution. The operator places himself on the right side of the bitch.

The first stage is to insert the fingers of the right hand through the inferior commissure of the vulva in a vertical direction, approximating the meatus to the vulvar aperture as far as possible, and at the same time to introduce the speculum with the left hand. The speculum is then opened within the vagina; and the meatus is easily seen in the boundary of the vaginal and vulvar mucous membrane.

When the meatus is seen, continue holding the speculum with the left hand, and withdraw the right hand to take up and introduce the lubricated catheter into the meatus.

The catheter is then passed some two or three centimetres (= about from  $\frac{1}{4}$  in. to  $1\frac{1}{2}$  in.), and withdraw the speculum. Nothing now remains to be done but to go on introducing the catheter till the urine is seen issuing.

Gago says that this technique, alike from the position and immobility of the animal, the position of the operator, and the illumination of the region, is very advantageous for different operations and for the introduction of a cystoscope. To avoid movements in very sensitive animals, a vulvo-vaginal anaesthesia should be obtained by means of a 2% solution of novocaine. This is done by pressing the vulvar lips together till only a very small aperture remains in the superior commissure, and passing the point of the syringe containing the solution through this orifice.—(*Revista de Higiene y Sanidad Veterinaria*).

## INTRAVENOUS INJECTIONS OF COLLOIDAL SULPHUR IN ACUTE ARTICULAR RHEUMATISM.

Lœper and Vahram made a communication upon this subject to the Société médicale des hôpitaux in 1915. Their observations were made upon seventeen human patients attacked by acute rheumatism of varying gravity, to whom colloidal sulphur was administered by the intravenous route.

The sulphur was administered in doses varying from 1 c.c. to 3 c.c., and was very well supported by all the patients. The treatment always produced from the day of the injection, and sometimes two hours after injection, a notable relief from pain. In addition, after a more or less sharp reaction, the temperature always became lower than it had been previous to the injection.

In benign cases recovery was obtained after one or two injections. In more serious cases four or five injections were required; and one grave case received eight or ten injections before recovery took place.

The pain diminished in the first place, and the inflammation afterwards. The authors were also able to see the gradual disappearance of a pleural calefaction and of a rheumatic pulmonary congestion; also that of an albuminuria which salicylate treatment had failed to cure. They never noticed cardiac complications, or any new attack in a previously infected valve.

The authors advise that injection into the veins should be practised whenever possible, commencing with small doses of 0.5 c.c., and increasing the dose daily until 2 c.c. is reached.—(*Revista de Higiene y Sanidad Veterinaria*).

## THE HÆMOCONIAS.

J. Maynar contributed an account of these imperfectly understood bodies to the *Treballs de la Societat Biologia* for 1916. Müller, of Vienna, describes under the name of hæmoconias some colourless particles, very refractile, less than a micron in diameter, and animated by Brownian movements, which are encountered normally in the blood serum. Their size renders them visible by an ordinary microscope provided with a good objective; but they are much more easily seen when a dark ground condenser is employed. Nothing certain is known of their genesis; but their aspect and the circumstances of their appearance suggest that they are allied to the fats, or, more correctly, lipoids.

Müller considers the hæmoconias to be constant elements in the blood, never absent in healthy individuals, although variable in quantity. He describes them as brilliant spherical bodies of a maximum diameter of one micron, colourless and very refractile. They are not retained by the net of fibrin, and are less dense than this and than the blood serum. They are not soluble either in acetic acid or in ether.

Stokes and Weggefath have noted the variety in size which hæmoconias present, and affirm that they augment in subjects who have ingested toxic

or alcoholic drinks. According to these authors, the hæmoconias have their origin in the disintegration of the eosinophile and neutrophile polynuclear leucocytes. Müller, on the contrary, believes that they are elements preformed in the blood.

Neumann has observed augmentation of the hæmoconias after the ingestion of fat, and has seen that this phenomenon is slower in old subjects, and slow or absent in diseases of the digestive tube or organs concerned with the digestion of fat.

Léva considers that the number of hæmoconias depends upon the quantity and kinds of fat ingested.

Agnaud and Jeantet state that they have seen plasmas destitute of hæmoconias. They believe that these bodies have very diverse sources of origin.

Cottin believes that the hæmoconias have a double origin, the majority being derived from fats, while a certain number are intraleucocytary in origin. He thinks that the examination of the hæmoconias may help in the diagnosis of certain diseases of the digestive tube.

Lemierre and Brulé have recently carried out interesting studies upon the importance of the presence of hæmoconias and the determination of their quantity. They have reached conclusions analogous to those of Cottin.

In modern works on physiology, little or no importance is attached to these bodies.—(*Revista de Higiene y Sanidad Pecuarias*).

W. R. C.

THE BEARINGS OF MARSHALL HALL'S DISCOVERIES ON ORTHOPÆDIC PRACTICE. By PROF. ARTHUR KEITH, M.D., F.R.S., Conservator of the Museum.

[The fifth of a Series of Lectures on the Anatomical and Physiological Principles underlying the Treatment of Injuries to Muscles, Bones, and Joints. Given at the Royal College of Surgeons of England, November-December, 1917.]

When Marshall Hall first announced his discovery of reflexaction, at a November meeting of the Zoological Society of London in 1832, he was a man of 42, a consulting physician with a considerable practice in London. He was born of a Saxon Midland stock—with an infusion of that hybrid strain which reached England through Normandy. His father was a cotton spinner and bleacher near Nottingham, the first in England to use chlorine for bleaching cotton. Marshall, at the age of 15, was apprenticed to a chemist or druggist in Newark, but in 1809, four years later, he became a medical student at Edinburgh, where he spent five years, three as a student and two as a resident in the infirmary. After two years as a physician in Bridgwater and eight in Nottingham, he settled in London in 1826.

In the course of experiments on the circulation in capillaries he made a chance observation which directed his attention to the nature of the functions of the spinal cord. He had cut off the tail of a salamander, and happening to touch its skin observed that there was a quick movement in response. That response Marshall's predecessors had often seen happen, but it immediately excited his attention because it was taught in his time that a muscle could be stimulated to action in three ways only—either by touching or stimulating it directly, or by stimulating the nerve, or by a volitional stimulus from the brain. He knew that the movement he had

evoked in the salamander's tail was due to none of these three causes; there must be a fourth way of calling muscles into action, and, as was his wont with exceptional cases, he followed up the clue. He destroyed the part of the spinal cord which lay in the detached tail, and found, on touching the skin, no movement could be elicited by touching the skin. He thus was led to suspect that in the spinal cord there resides a power, or mechanism, for the production of such movements as he had witnessed in the salamander's tail. To test his guess he took a snake and cut its spinal cord across, just behind the head, thus separating the brain, the recognised centre of muscular machinery, from the body. The snake remained perfectly still until he touched it, or a puff of wind struck it, or until the table was struck on which it lay, then the snake moved and kept moving until he wrapped it in cotton-wool and thus brought it to a standstill by protecting it from all external stimuli; so soon as it was brought to a standstill and its skin was protected all movements ceased. He then cut off the head of a turtle, and found that on touching the nose, which he knew from Bell's teaching to be a respiratory area, the floor of the mouth executed the respiratory movements which occur in one phase of breathing in turtles, but that when he destroyed the medulla oblongata, he could no longer elicit the respiratory act. He concluded that when the nose was stimulated by touch, a message was carried to the medulla by the fifth nerve, and therein a centre excited another message which was reflected along the motor nerves which control the muscles of the mouth and throat. He pictured in his mind an arc of nerves, and recognised that a stimulus was necessary to produce the reflected or reflex muscular act.

He then exposed the spinal cord of the headless turtle; he touched the spinal cord with a needle: the limbs were thrown into movements; messages, he concluded, must have been excited which had passed up and down the cord and been reflected to the muscles of the limbs. He touched the posterior roots of a fore, and then of a hind limb; the limbs were thrown into movements; he exposed and touched the nerves exposed in the trunk: movements of the limbs and body followed. He touched the skin of the trunk and of the limbs, and with each prick found that the movements evoked by stimulation of the skin were more vigorous than those which followed stimulation of nerves, the nerve roots, or even the cord itself; evidently the skin was the chief end-station for evoking such movements. He noted, in the headless turtle, that the sphincter of the anus retained its normal tonic power and function, but when he destroyed the hinder part of the spinal cord all tone and contraction disappeared from the sphincter. The power or mechanism which regulated the tonus or function of a sphincter was clearly resident in the spinal cord. On pricking the headless turtle he could evoke movements in the limbs; it was also clear that in the spinal cord there was resident a mechanism which could time and regulate the contraction of muscles. And lastly and for our present purpose he made a most important observation—when he removed the spinal cord from the headless turtle the limbs became limp, all tone and degree of contraction disappeared from the muscles of the limbs. That passive contracture of muscles which can work such dire deformities in diseased joints was, on Marshall Hall's showing, to be traced to a disordered function of the spinal cord. The spinal cord regulated the balance of the limb muscles and determined the posture of joints.

Marshall Hall was elected a Fellow of the Royal Society in 1832, and on June 20th, 1833, he read to it his paper "On the reflex function of the medulla oblongata and medulla spinalis," in which he demonstrated the existence in these parts of "a principle of action not hitherto distinguished with sufficient precision." We

have to remember that in 1833 knowledge of the finer structure of the central nervous system was crude and imperfect; yet he pictured an arc system, and grasped the full bearing of his discovery on the realm of medicine and biology. He had an instinct for signpost facts and critical experiments. He saw that the reflex function of the cord and medulla could be exalted—by opium in the frog and strychnine in the mammal; that the manifestation of tetanus and hydrophobia received a rational explanation for the first time. Asthma and epilepsy he also wished to bring within the scope of his reflex law. The excito-motor or reflex function of the spinal cord he found to be more easily excited in the young than in the old; if a teat touched the lips or a finger pressed the palm of a newly-born child, it was grasped by the lips or fingers. The anencephalic human fetus he regarded as a purely reflex mechanism. He observed how all the entrances and passages at the front end of the body, all the muscles and operations connected with the entrance of food and breath, were presided over and manipulated by his systems of reflex arcs. The action of the canals and muscles at the hinder end of the body were regulated by a similar system; defæcation, micturition, parturition were reflexly controlled acts. He found he could elicit such acts by stimulating the mucous linings of these canals; tenesmus, strangury, renal and biliary colic, the localised contractions of the belly wall, and manifestations of sympathetic pains which accompanied diseases or disorders of the intestinal tract were all brought by him within the scope of his new law. He found that reflexes could be set up by stimulation of the dura mater, pleura, and peritoneum; the muscular disturbances which may attend the eruption of teeth or the presence of worms in the rectum could be explained on his newly discovered system of reflex arcs. His conclusions, which must concern us now, relate to the muscles of the limbs; they, too, were controlled by the action of stimuli speeding along his postulated system of reflex arcs. Stimuli which arose in the moving limb were carried to the spinal cord by "incident" or excitator nerves, and were there "reflected" along the outgoing or motor nerves to the muscles. Each contact of the foot with the ground he supposed to call forth a new series of movements. At first he believed that the "tone" of muscles was also a true reflex manifestation, but later he regarded the tone of muscles as a function of the cord, manifested independently of the arrival of peripheral stimuli.

Marshall Hall, as a physician, desired to be Nature's servant—a sincere and outspoken servant if not a very humble one. "I am persuaded," he said, "that a knowledge of the healthy body action is the only foundation for practical medicine and the only remedy for quackery." "A mere practical man is a quack," was one of his aphorisms, yet there never was a man so misconstrued as Marshall Hall was by his contemporaries. The blame is not to be saddled altogether on them, for he had an unconscious art of rousing antagonism, jealousy, and mistrust. We can hardly wonder that John Hilton preferred to think of nerve trunks than of spinal centres as the functional elements which presided over the muscular system of the body. Neither he nor the line of surgeons which followed him perceived that Marshall Hall had given a new basis for the diagnosis of all disordered actions of muscles, and a sure principle in which a rational means of treatment could be based for the recovery of deformed and disabled limbs. Nay, I would go further. The full bearings of Marshall Hall's discoveries, and particularly the significance of the further investigations made by those who have so brilliantly explored the field which he had opened, have not yet been fully utilized by modern orthopædic surgeons. Marshall Hall made it impossible for us to think any

longer in the terms of single muscles, bones, and joints. All of them in the living state are combined into a functional whole by the spinal cord and its system of reflex arcs.—*The Lancet*, Jan. 5, 1918.

### VETERINARY FEES.

To the Editor of "The Veterinary Record."

Dear Sir,—We should like, through the medium of your valuable paper, to give the members of the veterinary profession, an outline of what the veterinary surgeons, in this part of Derbyshire and Staffordshire are doing.

We had a meeting last spring and adopted the following scale. We may say we have had no complaints, and everything has passed off quite satisfactorily.

"We, the undermentioned Veterinary Surgeons, on account of the heavy expenditure incurred in the working of Veterinary practices have found it necessary to amend our fees subject to other local practitioners agreeing to the following arrangement:

Mileage—Minimum 1/3 per mile. Visits—Minimum 3/6 Night Visits—8 p.m. to 6 a.m. 50 % extra.

General Practice—		£	s.	d.
Foaling cases	minimum	1	11	6
Calving cases	"	1	1	0
Removing Cleansing, Mare	"		10	6
" Cow	"		7	6
Milk Fever Inflation	"		10	6
Mileage and Medicines extra.				
Tuberculin Injection	minimum	1	1	0
Anti Abortion	"		2	6
Swine Fever	"		2	6
Taking Blood Samples	"		2	6
Intra-Tracheal Injection	"		1	6

Medicines—Aperient Drinks 1/6, Cleansing Drinks 1/6, Colic Drinks 2/6, Lotion 2/6, Liniment 2/6, Blister 2/6, Cough, Fever, and Worm Powders 4/- per half-dozen, Balls 1/6 ea., Cattle Powders 1/- ea., Inserting Pessaries 2/6 ea., Sale of Pessaries 2/- ea., Minima.

Insurance Fees for examination of each animal 10/6, unless insured by Veterinary Surgeon himself as agent.

Certificates (Fire and Lightning) for Mares and Cattle £1 1s. 0d.; for Sheep 10/6—and Mileage.

Castration and Docking—Castration 15/- each Colt; Docking 5/- each animal.

Castration of Calves 2/6 each, Yearling Bulls 7/6, Bulls, 2 years, 10/6. Minima.

Alex. Levie, Derby.  
J. T. Abell, Derby.  
— King, Derby.  
H. Fairer, Derby.  
Jno. Hawksworth, Etwall.  
F. Aulton, Tutbury.  
J. C. DeVille, Uttoxeter.  
C. J. Barnes, Cheadle.

H. McIntyre, Leek.  
E. Harrison, Bakewell.  
J. B. Howe, Wirksworth.  
R. Murray, Rugeley.  
Michael Sadler,  
Burton-on-Trent.  
Duckwork & Prince,  
Ashbourne.

We also send out our accounts—

Professional Attendance and Medicine  
from

and give no particulars, this has been our practice for some years.

If you think this will in any way assist the different Veterinary Medical Associations, in their endeavours to raise the fees, will you kindly insert in your next issue of *The Veterinary Record*.—We are, yours faithfully,  
DUCKWORTH & PRINCE.

Ashbourne, Derby, Aug. 30.

## BLACK-QUARTER—A QUESTION.

Sir,—I would like to ask through the medium of *The Veterinary Record* if "Black-quarter" has been seen affecting the tongue in cattle. I was recently called to a three-year-old cow. I found her down, unable to get up, and the tongue swollen up to such an extent that it completely filled the mouth; it was quite black; there was also an oedematous swelling under the jaw: temp. normal. The cow was quite all right the day before, and was found as described above in the morning. I examined the blood for anthrax with a negative result. I made an incision into the swelling under the jaw but the blood was quite normal, but on cutting into the tongue black, tarry blood exuded.

I have had a good deal of experience with "black-quarter," but I have never seen the lesion in connection with the tongue before.—Yours faithfully,

W. E. LITTLE, M.R.C.V.S.

## The Supply of Drugs.

The following appreciation of the position of the supply of drugs is taken from the leader columns of *The Lancet*. It is based upon an address by Mr. C. A. Hill, President, at the annual meeting of the British Pharmaceutical Conference.

It remains to be seen if our Government will recognise that, in the matter of manufactures, it is their plain duty to use the powers placed in their hands to protect our own people. Education of the public in these matters proceeds but slowly; and public opinion appears to be the only possible lever to move a Government.

"It is true that all drugs are relatively scarce and many of them very costly at the present time, but those which are absolutely unprocurable can be counted on the fingers of one hand, while it is perhaps safe to say that not a single essential drug has entirely vanished from the shelves of our chemists' shops—a tribute to the power of our Navy. When the market sections of the drug papers speak of a drug as being scarce it must not necessarily be inferred that the drug is being produced only in small quantities; the accurate inference is that the quantity available for distribution to the civil population is greatly reduced; the demand for drugs from the medical services of our own and our Allies' Armies has to be met first. Then, again, it is common knowledge that glycerin is difficult to obtain and that castor oil of the best quality cannot be bought in the open market. They are being produced in quantities far exceeding the pre-war output, but the whole of the production is required for purposes other than those medicinal. Trading vessels are bringing to port those vegetable drugs that cannot be produced in our soil and climate, and that although freights are amazingly high, cargoes much reduced in weight, and ships less frequent and longer in passage. If there is no Turkish opium to be had there is a sufficiency of Persian; if we do not import quinine from Germany we can secure a proportion of the product of the Dutch factories, or we can make quinine here from the cinchona bark of Java.

## SYNTHETIC PRODUCTS.

Germany had secured a practical monopoly of the dye industry, and the synthetic production of drugs was an offshoot of that industry. When war broke out nobody foresaw how long it would last, and nobody appears to have begun at once to make preparations to produce synthetic drugs on a scale adequate to supply the country's needs in the event of a long war. The American chemists were not hampered like our own manufacturers were, and they got to work before us. But the necessity of establishing a fine chemical indus-

try in this country was recognised in due course. In France, Spain, Holland, Japan, and especially in Switzerland, and even in some of our overseas dominions, the drug industry has now been established. The result is that the world has been made able to make itself independent of Germany; and if it can do this in war-time we may be sure that it will be able to do it when labour becomes plentiful and the scarcity of raw materials is no longer a factor to be reckoned with. In his altogether admirable address at the fifty-fifth Annual Meeting of the British Pharmaceutical Conference, Mr. C. A. Hill, the President, mentioned salicylic acid, aspirin, phenacetin, hexamine, and saccharin as substances which are being produced here on a regular scale. He did not extend the list further, but he said flatly, that "whenever a particular substance has been required for a particular purpose, British chemical science plus British chemical industry have not failed to produce it in requisite amount and of requisite purity within a reasonable time."

It is important to add Mr. Hill's proviso that, "questions of cost apart, the thing can be done." Lord Balfour's Committee on Trade after the War recommended that during a specified period British manufacturing chemists should be given very generous protection, so as to encourage them to establish here the synthetic drug industry on a large and permanent basis. This class of drug can and should be produced here at a price which will allow them to be sold for sums approximating to those which they would fetch if imported from abroad.

The President of the British Pharmaceutical Conference in his address did not make the mistake of leading us to think that we had made any remarkable progress in the synthetic drug industry: the manufacture of some of the drugs mentioned has been, as he told the Conference, an industry *ad hoc*. Obviously this will not meet after-war conditions, for the production of synthetic drugs on an economical scale must necessarily be part and parcel of a large and general scheme. It is in the imaginative lay mind that the danger lies, and it is to be hoped that the Exhibition of British Scientific Products now being held at King's College will not have the effect of impressing the public with the belief that so far as the production of drugs is concerned our difficulties are over. It is clearly demonstrated that British manufacturers are thoroughly capable of supplying us with products of a quality as good as, if not better than, those hitherto supplied from foreign sources. Their patriotic enterprise deserves all the encouragement it is possible to give; but it is to the great dye factories, rather than to the druggists, that we must look for the development of the industry: a successful synthetic drug industry depends on a successful dyestuffs industry.

## The antecedents of the Hackney.

Among the many discussions in the Breeders' journals, on the origin of various breeds, the Hackney comes in for a full share. The following is part of a long letter to *Live Stock Journal*, which appeared over the signature of Hugh Brooke.

"If I remember right, when the Hackney of to-day was first boomed he was called the Norfolk Hackney. May I suggest that he was the Pack Horse of the Middle Eastern Counties? When I was a youngster he was little known outside these counties. I remember he was then spoken of as a cob in build, about 14 h. 2 in. or 14 h. 3 h., and a good roadster, with much action. Pack Horse he was in the old days. Hackney is simply a word meaning 'common,' or 'much used,' or, shall I say, the general purpose horse? Now, the general purpose horse of the old days had to carry a great weight as

quickly as possible over heavy roads; such were the half-legged horses I spoke of, and the use of them on the different indigenous breeds of pony in their several districts I submit produced the slightly varying breeds of Pack Horse; the only distinct breed of Pack Horse being that bred in Norfolk—the general purpose nag of that part of the world.”

Another writer, J. P., contributed a long article, a hypothetical etymology of Hackney. From it we have taken the following:—

“The saying is ascribed to Sir G. C. Lewis, the eminent Victorian politician and philologist of the early sixties, that ‘by means of words we can look into the minds and read the thoughts of men who have lived ages ago.’ This statement, hard of belief though it may be to the non-philologist, is nevertheless true, and sets forth in a concise manner the means by which the derivation of any one word is attained. Take the case of ‘Hackney,’ for example. Could we trace this word to its source we should not only be able to tell the people who originally coined the word, but from its signification we should also be able to ascertain the train of thought which led to its formation.

The late Mr. H. F. Euren, the late Sir Walter Gilbey, and a host of other writers have at one time or another tried to penetrate into the hidden mysteries of Hackney history. Not one of these writers was an etymologist; they were content one and all to derive Norman-French *haquenée* from the Latin, *equus* a riding horse, and nag from the Saxon *hnegan*, to neigh, but they got no further forward in their quest of knowledge. Why? Because these so called derivations are not derivations at all.

From whom did the Norman-French derive their word? The French language, as the student knows, is composed of Latin, Gothic, and Celtic words in the order of importance named, and it is a curious fact that the French literary language of to-day comes from the language of the Normans, who consciously or unconsciously had a part in helping to mould the discordant elements into one grand harmonious whole. The Norman-French word ‘*haquenée*,’ as it stands, is a problem which no etymologist has ever been able to solve. No one has been able to determine whether it is a noun, an adjective, or past participle feminine; nothing, in fact, can be made of it; but to the writer it appears to be a corruption or phonetic rendering of another word not yet determined. Take part of the word—‘*haquen*.’ *Haquen* cannot be connected with any Latin or Celtic word, but is found to equal the Modern German *haken*; but, finding it in use in Gothic times, it may fairly be claimed as a Gothic word. In Modern German *haken* signifies a hook, that which is bent or curved in the form of a hook. Asking the question, ‘What is it that the Hackney bends or curves in the form of a hook?’ the man who knows his horse would promptly reply, ‘the knee,’ and knowing that ‘*kniu*’ in Gothic signified ‘knee,’ the full form of the word would stand as *haken-kniu*, and in this compound word the ultimate origin of Hackney stands revealed.

The Goths would appear to have been veritable Hackney enthusiasts, for in whatever country this remarkable people are known to have been there is evidence to show they carried the horse with them.

With this derivation the word Hackney might appear in our English Etymological dictionaries somewhat as follows:—

Hackney: Old English forms, *hackeneie*, *haquenaie*, *hackeneye*, *haquenée*, *haquenée*, *haknay*, *hakney*. [In Gothic, *haken-kniu*, from which all words in connection with Hackney, are derived, viz., Ital. (*h*)*acchine*, *chine*; Span. and Port., *hacanea*; Old French *hequenée*, *haquenée*; Dutch, *hakhenij*. In Gothic, *haken*, to hook or

bend in the form of a hook, and *kniu*=knee. As a term applied to a horse it signifies one that, when in action, bends and rebends the knee in the form of a hook. This action is peculiar to the Hackney, and serves to distinguish it from all other varieties of horses, ancient or modern, the wide world over.]

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

Edwd. H. Brogan, Lusaka, N. Rhodesia	£1	1	0
Hugh C. Jagger, Lt.-Col. A.V.C.	1	1	0
W. F. McConnell, Strabane	1	1	0
T. Parker, Newcastle-on-Tyne	1	1	0
William B. Whigham, Argentine	5	5	0
Previously acknowledged	970	13	11
	£979	17	11

### Sensibility of Chemical Tests.

No published data appear to be available as to the limit for the usual alkaloidal reactions on the extracts obtained by shaking out an extremely dilute, alkaline, aqueous solution of a free alkaloid with an immiscible solvent. Experiments were made with 200 mls of water, containing various known minute quantities of alkaloids. This was rendered alkaline with 0.5 Gm. of anhydrous sodium carbonate, and shaken out with 10, then 5, mls of chloroform. The bulked chloroform extract was evaporated, and the residue taken up in 1 ml of sulphuric acid 1:10. The acid liquid was divided into three watch-glasses. To one of these a drop of Bouchardat's reagent was added; to the second, a similar quantity of Tanret's reagent; and to third, of Sonnenschein's alkaloidal precipitant. In the first two an almost immediate opalescence or precipitate, and in the third an ultimate amorphous precipitate indicated the presence of an alkaloid. Under these conditions the presence of 0.0001 Gm. of alkaloid in the 200 mls of water, or 1:2,000,000, could be readily detected. This was not the limit of sensibility. With the reagents above named, it was at least three times greater than above indicated. In the case of aconitine, a positive green reaction was obtained from a dilution of 1:4,000,000. For the ordinary detection of alkaloids in water, therefore, reliable results may be obtained by testing as little as 100 mls of the original sample. This has been proved to be the case with aconitine, atropine, brucine, cocaine, colchicine, eserine, pilocarpine, strychnine, veratrine, and conine; in fact, all the commoner toxic vegetable bases. Under these conditions, stagnant water and well water containing putrefying organic matter gave no positive reactions for alkaloids.—L. LAUNOY (*Comptes rendues*.)

The quantity of copper sulphate usually recommended for destroying growths in ponds is one in three millions, a proportion which is said not to destroy fish or render the water dangerous to human life.

### Treatment of Scabies (human) with Chlorine Gas.

It was observed during the training of troops in gas drill, necessitating exposure to the fumes of chlorine, that those infested with scabies were rapidly cured. Experiments were then made directly on cases of this nature, exposing them, protected by gas masks, to an atmosphere containing 1 per mille of chlorine. The best results were obtained when four or more successive exposures to the gas were given, and usually four were sufficient, given on the first, second, fifth, and sixth day. In some cases this treatment caused a very irritable condition of the skin about the scrotum and axillae. This passes off one or two weeks after treatment. The method appears to be certainly much more efficacious than the use of sulphur or sulphurous acid, the hitherto most approved remedy.—Capts. G. H. Clark and H. G. Roper (*B.M.J.*, 1917, 2, 113).

### Aldershot Command Horse Show.

The first of what is hoped will be a long series of annual horse shows was held on Wednesday, 28th ult., at the Army Athletic Ground, Aldershot, under the patronage of the King and the presidency of Brigadier-General Sir Archibald Murray. The proceeds were devoted to the Blue Cross Fund for helping horses of all nationalities at the war, and Wednesday's effort should contribute at least £1000 to that praiseworthy object.

From start to finish the show was an unqualified success; the organisation and ring arrangements perfect, and reflected the greatest credit on Maj. H. F. Faudel-Phillips and his fellow stewards. The attendance was a

magnificent one, the military element largely predominating, although there was a fairly large crowd of civilians and many ladies present. Judging began at 9 a.m., under grey skies and with occasional rain squalls, but by noon an improvement began, and the remainder of the programme was got through in perfect weather.

The entries numbered over 300. Although it is commonly believed that all our best horses are now overseas, one could scarcely credit it in face of the outstanding merit of most of the exhibits. The light and heavy draught horses especially were of high quality, and, in spite of "rations," were turned out in what looked nearly up to pre-war condition. The riding horses were of excellent all-round quality, the chargers being of outstanding merit. The prizes included cups from the King, Lord Lonsdale, the President, Maj. Faudel-Phillips, and the Directors of the International and Richmond Royal Horse Shows. There were some excellent jumping contests, competitors from Australia, New Zealand, and Canada taking part; whilst a tent pegging display and a parade of prize-winners, followed by the presentation of prizes by Lady Murray, brought the day's proceedings to a close. Special praise is due to Captain V. D. S. Williams, the hon. secretary, upon whose shoulders most of the organising work fell, and to whose unwearying efforts the success of the show was due.

Teams and pairs from Witley and Bordon took part. For the Officers Turnout (driven by ladies) Capt. W. K. Townson, A.V.C., took first, with a cup; and Major L. Auchterlonie, A.V.C., was reserve.

### Burley New Forest Pony Show.

The annual show of the Burley and District New Forest Pony and Cattle Society was held in pouring rain, but, in spite of the weather, there was a goodly attendance. Entries were more numerous than last year, and the classes were all filled. The first three events for New Forest mares and foals had a total entry of seventy-five. All the winning ponies had good bone and substance. Taking the class as a whole, the average was good, but there were fewer outstanding ponies than in the past. It was notable that several of the best foals were by those stallions which have won Board of Agriculture premiums.

Good as the classes for mares were, the feature of the show was the fine collection of colts and fillies running with their dams. It was generally agreed that no such show of foals had been seen at Burley, where foal cups and premiums have always been liberally distributed.

In the hack class, Dorothy, the winner, was a charming mare and a good mover. The New Forest ponies are capital riding ponies, and a little more time expended on their schooling would repay owners amply.

The cattle were the best show ever seen at Burley, and the judges spoke highly of the improvement in milking qualities. Heifers were distinctly promising. We now have cow which can forage for itself for five months of the year, and is at the same time a good milker. Prices are rising every week for these cows.

### OBITUARY.

At White House, Brewood, Stafford, on Thursday, Aug. 22nd, the wife of Capt. G. H. Barber, A.V.C., died after a brief illness of five days.

### Personal.

A marriage has been arranged between Maj. Jonathan Scott Bowden, A.V.C. (T.F.), Whitehaven, Cumberland, and Mary (Mollie), the daughter of Mrs. Logan, Lowwood, Windermere.

## The King's Fund for the Disabled. Who will follow His Majesty's lead?

To the Editor.

Sir,—His Majesty the King has been graciously pleased to give not only his name, but also the magnificent sum of £78,000 to the Fund which was recently inaugurated to assist disabled officers and men of the Navy, Army, and Air Force to become useful members of the community again.

We, the Trustees of the Fund, for whom I sign as Chairman, appeal to the humanity, the gratitude, of every one of your readers, man, woman, and child, for a subscription which will help to find a new place in civil life for officers and men of His Majesty's Forces disabled in the War, and for the widows and children of officers and men who have given their lives for us.

"Why doesn't the Government do that?" some readers will ask.

Briefly, a State Pension scale must be hard and fast. Outside that scale there is a great human field which the King's Fund can cover, in which the officer, the man, or the dependant can be put on his or her feet, and given a sound re-establishment in civil life.

A State Scheme must be a classification according to the type; the King's Fund passes beyond classification. and acts, not as a public official, but as a private friend.

The present facts are:—

We are receiving 600 applications a week. 2500 cases have been dealt with thus far. Where the officer or man has been trained by the Ministry of Pensions, or where there is a business given up for War Service, which he can restart, an adequate grant can be made.

The Fund is a Monument of Gratitude. It will cheer our gallant fighters to see that monument rising to £23,000,000—the amount aimed at. So let us, therefore, have the money—and quickly. Urgent cases are waiting.

The King leads off with his great gift of £78,000. Who will follow the King's lead?

Contributions should be sent to

THE KING'S FUND FOR THE DISABLED,  
WESTMINSTER HOUSE, MILLBANK, S.W. 1.

All cheques and postal orders should be crossed.

For the Trustees,  
(Sgd) JOHN HODGE, Chairman.

## Udder Disease in Dairy Stock.

The following appears in the current issue of *The Scottish Farmer*. The first question that suggests itself is—Has Mr. Scott made any effort to get the matter investigated. There is a Veterinary College in Glasgow.

"Sir,—I think it is time something should be done to combat this very serious disease. I understand that it was prevalent among dairy cows in the South of Scotland in May of this year, and now many dairy farms in Lanarkshire are affected. No one seems to have drawn the attention of the Board of Agriculture, veterinary surgeons, or dairy farmers to it.

In my opinion, if something is not done immediately to eradicate this insidious disease, it will mean ruin to many dairy farmers, and that milk will be unobtainable in many districts.—Yours truly,

Auchinlea, Cleland.

JOHN SCOTT.

## ANTISEPTICS.

In human and veterinary surgery alike, hardly anything is more subject to changes of fashion than the choice of antiseptics. Every experienced practitioner can remember antiseptics which, after being introduced with extravagant claims and enjoying considerable vogue for a time, have since fallen into disfavour. A few of these continue to retain a fair though usually fluctuating amount of confidence; the majority fall more or less into disuse.

The truth is that the actions of antiseptics have not yet been studied with sufficient accuracy and thoroughness. Most antiseptics owe their reputations to two recommendations—laboratory reports of their actions upon microbes *in vitro*, and clinical observations upon their effects in wound treatment. Both these methods of observation have serious limitations; and together they form an insufficient criterion of the value of any antiseptic. Tests of an antiseptic action upon a microbe *in vitro* obviously afford little indication of what will happen when the antiseptic and microbe meet in the very different media of the tissues and discharges of a wound. So far as clinical examination of wounds is concerned, there are essential points upon which no clinical examination can give any information of value.

There are factors in wound treatment which, though much worked upon of late years, have not yet received all the study they deserve, and even now are little appreciated by some clinicians. All clinicians know something of the great variety in species and virulence of the bacteria found in wounds; but not all have given sufficient thought to such problems as the chemical changes and modifications of germicidal activity which antiseptics in contact with wound tissues and discharges undergo, the exact action of different antiseptics upon the tissues, and the nature and effects of the chemical compounds which may be formed between the antiseptics and the wound contents. Some clinicians of the old school might regard these questions as "theory"; but they have an exceedingly practical bearing upon the subject, and their practical study is essential to the most efficient wound treatment.

Old methods of studying antiseptics and treating wounds are no longer adequate. It is now known that, in both, we can only approximate the ideal by frequently checking clinical observations by microscopic examinations of the contents of wounds. This, of course, is very often impossible in general practice, and probably always will be. Still, it might be practised more often than it is; and certainly every clinician might become better ac-

quainted with the results of recent studies of antiseptics and wounds than some are. There is perhaps no subject concerning which it is more important that the practitioner should familiarise himself with the most recent research.

## HODGKIN'S DISEASE IN THE DOG.

The case recorded by Mr. Wm. Pauer in last week's issue reminds me of four similar instances encountered in my practice during the last year. The first, a fox terrier six years of age, a very plethoric animal, in which primarily the submaxillary glands were the only structures involved; the swellings were very large, interfering with respiration and causing a good deal of distress. The animal was under treatment for two months; later the axillary glands became involved. Treatment was of no avail, and owing to distress involved in breathing the patient was lethally. Throughout the whole course he maintained his condition. Post-mortem examination was not agreed to, so that the condition of the internal organs could not be demonstrated. This case taught me the futility of attempting treatment, and although I have heard from other practitioners of recoveries I am inclined to doubt the accuracy of the diagnosis.

The second case was a Scottish terrier in which the submaxillary and cervical glands were the centres of disease: general condition of the animal good, but anæmia marked. My former experience proved to me the inadvisability of attempting treatment. This was the second dog the owner informed me she had had affected with this complaint.

The third is a fox terrier, alive to-day, receiving no treatment since the first fortnight of coming to my notice, six months ago. The submaxillary and cervical glands only are involved, as in the preceding case, and the disease so far does not seem to progress. Although anæmic, his general spirits and appetite are good, whilst the owner is contented to keep him alive in the absence of pain.

The fourth and latest case was the most advanced case of the disease I have yet witnessed, it was a mongrel sheep dog. The submaxillary glands were immense, the cervical glands most prominent, the axillary glands and inguinal glands all badly affected, the latter so considerably on one side as to cause marked lameness. The condition otherwise was good, the animal, a fat one, that palpation of the abdomen revealed nothing. This would have been a useful case for demonstration to students. A candid opinion was given and the animal disposed of. A post-mortem examination in this case might

have been effected, but stress of work would not allow of this at the time.

This disease may be of interest to some; personally I hope not to encounter it again. It is most unsatisfactory to have surprise expressed at one's inability to treat the case, and disappointment marked after an extended trial.

GEORGE YATES, F.R.C.V.S.

#### ABOUT PATENT MEDICINES.

It is regrettable that nothing is done to stop the administration of secret remedies to animals.

Some practitioners declare that no such medicines are used by their clients, and that they have succeeded in converting owners to believe that stock remedies supplied by a veterinarian are much more beneficial.

Nothing but legislation that demands the disclosure of the prescriptions on the labels will ever stamp out this evil. Legislation should be sought by the R.C.V.S., at the earliest suitable opportunity; and meanwhile, veterinarians should collect reliable information concerning cases that come under their notice in which patent medicines have proved harmful. The writer of these notes has diligently searched British veterinary literature for clinical records of harm arising from patents, and is astonished that so few cases are recorded.

The owners of patent medicines undoubtedly have commercial success, judging from the large sums of money they leave behind them. But when we consider the goods sold by these people and their utility to stock owners, we are forced to admit that they have been weighed in the balance and found wanting.

Veterinary Colleges that at present carry on practice and shoeing forges in open competition with practitioners and shoeing smiths would be more usefully employed as institutions wherein patent animal medicines were analysed, and where literature dealing with the ascertained analyses could be compiled and issued to the profession.

Quack medicines, in order to sell, require a considerable amount of advertising, and on an average 50 per cent. of their retail prices is expended in advertisement. What would be said of a commercial system in which our daily needs, our books, education, travel and sport cost us various sums whose halves were invariably expended in newspaper and similar advertisements? Only to a race of lunatics would such a thing be possible. The whole business is like a great show ship—vast sails and precious little cargo.

When a quack medicine cures an animal, we may safely assume that the ailment was a simple one, and that recovery would have taken place without medicine. In serious ailments, their administration, besides being dangerous, is extremely absurd.

The stock-owning community is on the whole nearly entirely ignorant of physiology, pathology, and medicine; and the boastful and untruthful claims made on behalf of patent medicines are specifically designed to match that ignorance. If

it be absurd that such people try to doctor animals, it is much more absurd for them to administer drugs of which they know very little.

The efficient action of a medicament depends upon a knowledge of three things:—

- (1) the nature of the complaint;
- (2) the nature of the substance administered;
- (3) the relation of the latter to the former.

Those are the fundamental principles of scientific medicine: they are grounded on reason, sanctioned by common sense, and confirmed by practice. It follows that when such principles are violated, there is a negation of science and reason, and the result is quackery, humbug, absurdity, and the likelihood of a good deal of mischief to the patient. For a person utterly ignorant of veterinary science to diagnose the complaint of an animal and then—absurdity upon absurdity—to administer a secret remedy is so preposterous as to stagger credibility.

It is well for veterinarians in districts where there is a ready sale for these medicines to think over the reasons why such medicines have gained a footing.

It may be owing to the fact that practitioners refuse to supply clients with stock remedies, as the more professional side of life is desired; or perhaps the stock remedies supplied do not fulfil their purpose; or—last but not least—the clients are more impressed with the neat manner in which the quack medicine vendor sends out his goods. There is much in making medicine appear as *medicine*, and with the quack this is a fine art. A black drink may appeal more to a farmer than a colourless solution of a valuable drug.

Frequently patent medicines contain turpentine well disguised with balsam of sulphur.

It is time we had a book on secret veterinary remedies published by the R.C.V.S.

“LAMANCHÁ.”

#### ABSTRACTS FROM FOREIGN JOURNALS.

A METHOD OF DESTROYING THE LARVÆ OF MOSQUITOES. By MM. ED. and E. SERJENT. Presented by M. LAVERAN.

Under Mediterranean climatic conditions, the average length of the life of mosquito larvæ in water till metamorphosed into the perfect winged insect is about three weeks (sixteen to twenty-five days).

The “breeding places” of mosquitoes (*gîtes*) are accumulations of water, sometimes of considerable size; such as lakes, pools, inaccessible marches, and large streams. Only the labour of the engineer that transforms the face of the land suffices to deal with these large breeding places. But sometimes breeding places of very limited size cause infestation of a whole region.

In a number of villages the maintenance of malarial mosquito breeding places is freely kept up by water flowing from small springs, fountains, small reservoirs, washing pools, and irrigation channels. Trickling streamlets grow and widen out to form pools in which the water is constantly

changed without any strong flow, and these form excellent breeding places for the anophelines.

Since commencing our first anti-malarial campaign in 1902, this type of breeding place has been dealt with by the recognised anti-larval measures, such as replacement by masonry and concrete, cleansing, maintenance of repairs, mowing of herbage, application of kerosene, the filling in of cattle hoof tracks, control of waterways and efficient drainage. For the last ten years, in the Tall region of Algiers, we have experimented with success with a new and simpler method of procedure.

It frequently happens that the breeding place is on the course of a single stream. On this we dig two channels which, each for a week in turn, carries all the water. The water is turned into either channel at will by a simple earth dam or a water gate.

Each channel in turn, during its week of use, is the home of egg-laying anophelines and hatching larvæ. Then comes the week without water, when the channel is dried by the heat of the weather—and the larvæ perish.

Each channel is alternately wet and dry for a week at a time, all the labour required being a few strokes of a mattock to break the one dam and rebuild it in the other channel, or double water gates may be used with advantage.

The arrangement may be varied: instead of using two channels, the water may be spread on the surface to the right or left by a series of secondary dams, in such a way that it may be absorbed by the ground or evaporated off within eight days. The water is not turned on to the same ground for some weeks. In this method little earth dams are used.

The method of drying off the breeding place gives excellent results with but very little attention, and expense is considerably reduced. At a very moderate estimate costs are reduced to a tenth of those of the usual anti-larval methods.

*Summary.* In the Mediterranean region, mosquito larvæ require a breeding place that is wet or moist for a period of about three weeks; if this permanent period is broken so that each portion is alternately wet and dry for a week at a time, the larvæ cannot survive.

A mosquito breeding place of a permanent character is not necessarily dangerous. The remedy lies in substituting two alternating ones for the single permanent one.—From *Comptes Rendus*, 165, 14, 436, 7, 1917.

FRAIS. EVELYN PLACE, B.V.SC., M.B.C.V.S.

#### THE TOPOGRAPHICAL DIAGNOSIS OF TRAUMATIC HÆMORRHAGES IN THE SPINAL CORD OF THE HORSE.

Frohner discusses this subject in the *Monatsheft für praktische Tierheilkunde*. The anatomical and topographical diagnosis of these cases is difficult, because the manual investigation is also difficult, and the estimation of the sensibility and of the reflexes is frequently unreliable. Contrary to what is seen in cases of infectious paralysis, cases of traumatic paralysis manifest themselves suddenly.

The mental life is intact, and the paralysis is generally bilateral and is often associated with paralysis of the bladder, rectum, and tail. To diagnose the localisation of the medullary lesion, it is necessary to know the disposition of the spinal motor centres in the distinct medullary segments (the so-called segmentary diagnosis).

A hæmorrhage into the dorsal, lumbar, and sacral medulla produces a motor paralysis of the posterior limbs, commonly in the form of paraplegia, due to disturbance of the nerve centres which animate the dorsal muscles and of those of the lumbar plexus and sacral plexus. If the hæmorrhage is in the cervical medulla, it especially produces paralysis of the anterior limbs (by acting on the nerve centres of the brachial plexus) and, in addition, paralysis of the posterior limbs. Hæmorrhages of the lumbar medulla cause paralysis of the posterior limbs, and at the same time of the bladder and rectum (motor centres in the lumbar medulla). In hæmorrhages of the sacral medulla of the cauda equina, paralysis of the sphincters and of the tail supervenes. Hæmorrhages in the region of the fourth cervical segment cause paralysis of the diaphragm, besides paralysis of the anterior and posterior limbs.

Clinically it is generally impossible to diagnose the precise nature of the anatomical lesion, because there are no certain clinical symptoms of hæmorrhage. Post-mortem examination alone places the existence of hæmorrhage beyond doubt. Fröhner, however, has diagnosed four cases, which he describes in detail. One was cervical, one dorsal, one lumbar, and the fourth sacral.—(*Revista Veterinaria de Espana*).

#### A CUTANEOUS REVULSANT.

Gacon has recommended the following formula for a cutaneous revulsant, saying that the preparation is very energetic and has no drawbacks. The composition is croton oil 4 parts, turpentine 20 parts, 90 p.c. alcohol 120 parts, and sulphuric ether 60 parts. This should be well mixed, and preserved in a hermetically sealed flask. When it is required for use the liquid should be limpid; if it is not so, ether should be added to clarify it.

This formula is employed with success in France in all classes of contusions, and also as a derivative in cases of angina, bronchitis, pneumonia, etc. It is applied by means of a cloth soaked in the liquid. The cloth is passed over all the indicated region in the direction of the hairs, care being taken not to go beyond this region. In a few days a cutaneous eschar is produced, which easily separates.—(*Revista Veterinaria de Espana*).

#### PHYSIOLOGICAL MUSCULAR ALBINISM IN CATTLE.

Chaussé reported his studies of this condition in the *Revue Pratique des Abattoirs* of 1913. Various observers, in the post-mortem inspection in the abattoir of adult cattle which had presented no symptoms of disease to clinical examination, have noted the existence of a generalised muscular degeneration, so pronounced that all the flesh has appeared of the colour of café-au-lait or of a clear salmon colour, giving it a certain resemblance to

veal. None of the authors who have observed this anomaly have studied it deeply; and, therefore, they have interpreted it differently.

Chaussé has carried out an anatomical and histological study of a case of this nature, and has convinced himself that, apart from the muscular decoloration, the carcass presented absolutely nothing abnormal. From this he deduces that these are cases of simple muscular decolourisation, perfectly compatible with an excellent general condition, and that there is no reason for condemning such flesh. The condition must not be confounded with certain muscular decolourisations of degenerative nature, which are generally localised in their distribution. —(*Revista de Higiene y Sanidad Veterinaria*).

#### EQUINE AMYLOID LIVER—RUPTURE.

Fröhner records one of these cases in the *Monatsheft für praktische Tierheilkunde*. It is known that rupture of the parenchyma of the amyloid liver is not rare, especially when the animal is affected with colic. This happened in the case under notice, in which death supervened in half-an-hour from internal hæmorrhage. As icterus was not seen, amyloid liver was not thought of; but rupture of an internal organ was suspected. Rectal exploration revealed the existence of rugosities in the intestinal coils, which might have been alimentary matter, but which really were blood clots. The liver weighed 15 kilogrammes (= about 33 lb.), and was fragile, soft, and grey-brown to yellowish-brown in colour. Its right lobe showed two ruptures. The liver, spleen, and kidneys were all amyloid. There were traces of an old pleuro-pneumonia, indicating a previous attack of pectoral influenza. —(*Revista Veterinaria de Espana*).

W. R. C.

#### VETERINARY EDUCATION IN U.S.A.

Reference has been made in these pages on several occasions to the continued upward progress of the profession in the States. The latest was a note from the May number of *Journal A.V.M.A.*, on the varying grades of professional colleges. The following excerpts are from a discussion on papers at the annual meeting of the A.V.M.A., from the August number of the *Journal*. They bring into notice several difficulties, some of which are not unknown on this side, but which they have to meet *de novo* and under differing conditions.

(Dr. Quitman): "I do not believe it lies within the effort of any veterinary college to turn every man out a specialist in every different branch. Dr. Turner evidently sees the veterinarian only through the army eye, while Dr. Bailey, in his paper, sees the veterinarian only through the eyes of a milk hygienist. It certainly would mean about a seventeen-year course to follow out the ideas of these two gentlemen, if every specialist had the same idea. In human medicine they do not turn out specialists. If a man wants to specialize in human medicine he has to continue his studies after he graduates. I think it is asking too much of a veterinary college whether it be a State university or a private school, to turn out men who are specialists in every different branch.

(Dr. Hoskins): You know in New York State we have nothing to say about the requirements of men entering veterinary schools there. The Board of Regents establish

the requirements for us. They require that they shall be graduates of four years of high school work and shall have seventy-two counts; and I am not yet convinced that high school requirements will solve the difficulty that we have been contending about for a good many years. In all large cities like the City of New York, the high school there does give a very wide latitude of instruction; but I have been disappointed considerably by the fact that many of these men who come to us with high school entrance requirements are still very lacking in the proper knowledge of the fundamentals. I have marked a good many papers in my time, as a member of the State Board, of men who came to the college without the entrance examination, but with the qualifications of high school men. I have been quite disappointed in a reasonable per cent. of those men that they did not write either an intelligent paper nor were they able to write correctly or to express themselves in their papers grammatically. I glory in the address of the President which we listened to this morning, because I always admire the man who preaches the gospel of discontent, since he is sure to get somewhere; while the man who preaches to those who listen to him that they should be contented with their lot does not get very far—in fact has commenced to retrograde.

When men come to us in our veterinary schools in great states like that of New York, or a great city like New York City, they come to us lacking, to my mind, a very essential thing. They come to us without a particle of knowledge of animal industry, with no knowledge of farm life, with no particular love for animals, but too many of them come to us with purely a commercial thought in mind. It is one of the difficult problems to eliminate that from these men's minds, and I have decided that this year, in opening the four years' course at the New York City Veterinary College, from the 5th day of September to the 26th day, we will devote that entire period with the four classes, teaching them and getting into their minds the thought that the field of veterinary medicine is not a commercial one, but is one of service—of service to humanity, of service that will bring them a rich reward in a feeling when they have closed their career that they have been helpful to mankind, that they have done something to lift the burdens off the shoulders of the great masses of people, and done something for what our President has spoken of, a world-wide Christianity.

Another point we might take notice of from our President's address is that we must realise the importance of maintaining our courses in keeping with others—with the courses of engineering and with human medicine. We cannot hope, understand, that the future of any of our men can have the possibilities of engineering that oftentimes brings great fortunes over night, nor the possibilities of human medicine in the great cities where men command as much as \$500 to wait upon the birth of a child on Fifth Avenue, or perhaps on Walnut Street of Philadelphia. Our men are going into a field that only promises perhaps with care and frugality and thrift a competence in old age—not riches or affluence; and we, who are engaged in the teaching of veterinary medicine, we who are trying to lift up veterinary medicine and build it up as we should must take into consideration, in dealing with student bodies, this phase of it.

[Dr. Hoskins has here touched upon three important features of veterinary education. The first concerns the preliminary examination in general education, or matriculation. It appears from the context and from the remarks of men who spoke later that alternative—in some colleges—to the high school certificate is a "general knowledge" exam. by the college. In Britain we have the same deficiencies in writing, in spelling, and in composition, but only in a comparatively small proportion

of the students. But small as that proportion may be, we should be better without it.

The next is an ethical proposition; but it is one that materially affects the attitude of the practitioner to his clients, and reflexly, the attitude of the public towards the profession generally. The men of education and right feeling who have become members of the profession naturally object to be put on a level with the illiterate trickster whose *only* idea is what he can "make" out of his clients. The professional man claims a suitable recompense for his skill and his endeavours on behalf of his patients.

The third consideration is, in a measure, also ethical; and is one that our members have acknowledged and adhered to in keeping up the standard of general education required from intending students.]

(Dr. S. Stewart): In some of the States, as you have heard to-day, a graduate of the veterinary college is granted a licence to practise upon presentation of his graduation certificate or diploma, which is recognised by the State board. In the State of Minnesota they do not recognise anybody's diploma other than to the extent that it makes the holder eligible to enter the examination for a licence to practise. Minnesota differs from any other State board of which I have knowledge, in that they believe it their duty to examine the candidate's basic educational qualifications as well as his scientific qualifications. The fact appears to be that about eighty per cent. of the men who have appeared before that State board in the last two years have failed to pass, largely because of their failure to meet the basic educational requirements as set forth by that board.

State boards have been guilty in some instances of some peculiar, eccentric catch question and they have been guilty of asking or propounding questions on theories that have long ago been exploded.

All that sort of thing can be eliminated if the State examining boards will get together and discuss the features of the examination which it is possible for them to give under the laws of the State under which they are operating. Some of these State boards have very little experience—the State board of Texas has had possibly two years' experience and it is made up of men who never did any teaching, and who have no ideas concerning the work of instruction. They may never have prepared a set of questions and may not know the difficulty of making questions perfectly plain; may know nothing of how to equalise the value of various questions in the various departments, which is a very serious trouble indeed. I believe if it were the province of this body to prepare such sets of questions and offer them as suggestions of what would be proper questions—fair to the student preparing to apply for a licence, and just as fair really in the State of Texas as in the State of Pennsylvania, it would be of very great advantage.

Just one more matter, and that is, whether State examining boards might not develop the students' knowledge by a practical examination as, for instance, if they should require him to pick up a horse's foot and examine the bottom of it and show that he knows how to go about his business; so that they could ascertain whether he could really put a bridle on a horse, or whether he knows about harness and how a double-team harness was put on for instance, so that he would show the examiner by his methods that he knew what auscultation and percussion really means and what might be learned by them.

[Dr. Stewart mentions the preliminary exam. with the condition that this State not only does not admit a diploma granted by another State Board as qualifying to practise in Minnesota, but also examines the candidate's educational qualifications—and apparently the course is justified. The State Boards are open to improvements in several respects; see his remarks on

questions. Though whether his suggestion that questions should be prepared by "this body" (A.V.M.A.) is quite the best way out is open to doubt.

The suggestion of further examination of a practical character is also referred to by other speakers.]

(Dr. Donaldson): In regard to the Minnesota examination board putting up an examination in preliminary education, I assure you some of the answers we get and some of the papers show that it was very necessary. I do not want to be very specific in this, but it is plainly evident that something is needed along that line. Not very long ago I had the 1917 prospectuses that were sent out to me from the different colleges, which tell what their entrance requirements are. Judging from what we get in Minnesota, some of those colleges are not coming up to what they say in their catalogues. There are institutions that are not examining their men properly before they go in. I am not advocating a high school education. As far as I am concerned I do not think it is necessary. I think, however, there ought to be a line drawn as to where a man ought to have education enough any way to understand the language that is being used in the college; and I think he ought to have enough education so as not to come up to the Minnesota State board and spell such words as stomach "s-t-u-m-i-k."

(Dr. S. L. Stewart): Again bringing up the subject of passing examinations, if you will go to the records of the students in the public schools and in the high schools you will find very few good spellers. They are exceedingly poor in spelling and in clear handwriting. I don't know how a veterinary college is going to turn out men who are good spellers and good copywriters unless they have attained these accomplishments in the public and high schools. It is a surprise to see the words that a high school graduate will mis-spell, and it is surprising to know that few people can really write a clear hand and make a correct copy. I think those things ought to be corrected in our public schools and in our high schools.

(Dr. W. E. Stone): Again, I do not believe that the majority of our veterinary faculties grade in the subjects of spelling and writing when they are correcting examination papers. Dr. S. Stewart has referred to the fact that the rapid taking of notes had a tendency to overcome good spelling and writing. I heartily agree with him, because I know that oftentimes in writing examinations I would abbreviate my word or write it regardless of the correct way of spelling, just so that the instructor could make out what I meant. If I had been corrected and a demerit put after such a word, the next time I would not have done that.

I would like to speak of another thing—reciprocity. I would hail the day with much delight when we could have a government board examination. All veterinarians would be glad of one universal board before which all veterinary students could go and take an examination and do away with the State boards entirely; or else have uniform State questions so that if a man registered in the State of Missouri he could pass into the State of Minnesota and practise. If it could be put into practice throughout this country it would be welcomed by all veterinarians and veterinary schools.

The discussion concludes with remarks by Dr. Hoskins. After referring to the mention of the late Rush Shippen Huidekoper, a graduate of Alfort School, in one of the papers preceding the discussion, said that Huidekoper, back in the early eighties, held the idea that men who were going to enter the veterinary profession should have certain training: he had hoped to see a veterinary school at the University of Pennsylvania with the first year of every entering student devoted entirely to determining his aptitude for the profession. He considered that a student ought to know a great deal about animal

life—all about taking care of horses: he would put him in the stable and teach him to use a fork, and the brush and curry comb, and to handle harness and saddle, and to ride. Dr. Hoskins continued: "I do sincerely hope that some such plan may yet emanate from some of our schools." Referring to remarks by Drs. Stewart and Stone, on reciprocity, he said, "I have no doubt that neither of these men are aware of the fact that we have wrestled with that problem for twenty-four long years: but I am glad to see that we are getting nearer to the only possible solution of it under our form of government. I am hopeful that the Federal Government will establish very soon some standards of requirement for the veterinarians acting under the Board of Animal Industry, for the men who are going into the army, into veterinary service, or any other position under our government."

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

A. Blake, Rangoon, Burma (1917, '18	£2	2	0
J. Garvie, Montrose	1	1	0
J. R. Greig, Capt. A.V.C.	1	1	0

#### The "Forest Horse" of Hampshire.

The importance of the native pony goes, I think, farther back than that continual inflow of Eastern blood which has been going on from the days of the Roman occupation up to the present day. Spain, Italy, Constantinople, Syria, Baghdad and Morocco have all contributed in almost all periods of our history. During the past twelve years I have been riding or walking about the New Forest examining the ponies, and there has come to me not only the realisation of the great part played in the formation of our ponies by the North African horse in his varieties, but also the belief that this was merely the superstructure, and that the foundations have yet to be discovered. Then I read Prof. Cossar Ewart's contributions to the history of the horse of this country, and it seems to me that in the New Forest, and that far wider forest district which preceded it, there must have been a more ancient race. Gradually I have come to see that the "Forest Horse" is the foundation on which the pony has—in these parts, at all events—been built up. I note the continual reappearance of the long head, the more or less concave outline of the face, the eyes placed rather high up, the size of the chestnuts and the recurrence of ergots, the long narrow nostrils, and the prehensile lips. The Forest ponies are all browsers on trees and shrubs, as well as grazers, and this enables the ponies to live, and sometimes to keep

in good condition, throughout the long winters and our bitter spring winds.

It is these ancestors which give to the ponies their extraordinary hardy constitutions and their quite remarkable soundness. I have never known a Forest-bred pony to fail to pass the Board of Agriculture test. Ponies of other breeds sometimes fail, but hardly ever our native-bred Forest ponies. Then, again, the Forest pony is a jumper not only of power but of resource. There was one well-known pony which could negotiate the most intricate Forest boundary fences and could get over a strand of wire. This ancient Forest breed has great powers of absorbing and assimilating outcrosses. When they met the Eastern horses, with the versatility characteristic of the Arab blood, their good points were assimilated and adopted by the ponies; and I could point out ponies now which have the quality of the Arab and the power and substance of the Highland or other sturdy breeds of Scotch ponies.

I think, from the recurrence of the type of head, the almost invariable chestnuts and ergots, that the foundation here was chiefly "Forest Horse." There was very little Celtic pony, and the type of head of the Celtic pony—square, small, alert—comes, when we find it, which is not very often, from the introduction of Welsh or Dartmoor blood, neither of which races leave much of their own stamp in the Forest. Again, the study of Professor Ewart's writings has left on my mind the impression that the "Forest Horse" was more intelligent and resourceful than either the steppe horse or the horse of the plateau.

One thing I have noted, but I cannot explain, is that in those districts where there has been much Arab blood the chestnuts, as one might expect, either become very small or not found at all, but the head—large, sensible, and from the front view narrow—always reappears. I account for this to myself from the impression I have that the last thing one breeds out is a plain head.—(From a letter by T. F. Dale, Burley, Hants, in *Live Stock Journal*.)

#### Cruelty Charge at Cheltenham.

At Cheltenham Police Court, on Monday, Sept. 2nd, the case in which William J. James, of Blackledge Farm, Leckhampton, was summoned for cruelty to a gelding by working it in an unfit state, and which had been adjourned from a previous court for the purpose of calling expert evidence as to the condition of the animal, was again before the Bench.

The testimony of Prof. G. H. Wooldridge, of the Royal Veterinary College, London, was that the cob was entirely unfit for any work. It was over 20 years old, lame in both fore limbs, and very much bent over on the knees. Bodily, its condition was good, indicating that there was no continuous pain, but any forced extension or flexion of the joints would cause pain, and such movements were inevitable in any work or fast progression. The Professor answered a number of questions put to him by Inspector Jowett, R.S.P.C.A. (by whom he was called), and Mr. Haddock, the Solicitor for defendant.

Mr. J. R. A. Jones, M.R.C.V.S., Gloucester, called by the defence, confirmed evidence given by Mr. Thomas J. Brain, M.R.C.V.S., of Cheltenham, at the previous hearing, contending that the animal, whilst unfortunate in its appearance, suffered no pain, and was quite fit for light work. It was, he admitted, a "most decrepit-looking old animal," but it looked a great deal worse than it really was.

The Bench gave a verdict for the prosecution, and in fining the defendant £3, they also ordered that the horse should be destroyed.—*The Echo*.

# ARMY VETERINARY SERVICE

The following is addendum to the dispatch from Lieut.-Gen. W. R. Marshall, Commander-in-Chief, Mesopotamian Expeditionary Force, which appeared in our issue of Aug. 31 (p. 71). :—

"Owing to the increased area over which this Force operates, to the amount of animal diseases existing in the territories conquered, and to the consequent danger of the animals of the Force becoming infected, it has been found necessary to increase the Veterinary administrative staff and to form extra Veterinary Hospitals. The results are most gratifying, and reflect great credit on this Department."

Extracts from *London Gazette*,  
WAR OFFICE, WHITEHALL, Sept. 6.

## REGULAR FORCES. ARMY VETERINARY CORPS.

Temp. Lieuts. to be temp. Capts. :—N. H. MacAlister (Aug. 15); J. J. M. Barry (Aug. 18); G. L. Bradley (Aug. 22).

Sept. 9.

Lt.-Col. (temp. Col.) G. M. Williams, c.m.g., to be temp. Brig.-Gen. while holding the appt. of Dir. of Vety. Servs. (Aug. 11).

Maj. (Bt. Lt.-Col.) J. J. Aitken, d.s.o., to be actg. Lt.-Col. while holding the appt. of Asst. Dir. of Vety. Servs. (June 22).

Temp. Capt. J. H. T. Kenyon relinquishes his commn. on account of ill-health, and is granted the hon. rank of Capt. (Sept. 10).

Sept. 10.

To be temp. Lts. :—B. T. Carmichael, H. W. Graham, B. R. Atmore, O. A. K. Snyder, C. H. Heslop, E. M. Hill, H. N. Howell, J. L. Heffron, J. B. Williams (late temp. Lt. Canadian A.V.C.) (July 24); C. R. Boast (July 25).

Sept. 11.

Temp. Lts. to be temp. Capts. :—R. Gorman (Aug. 24); F. McD. McKenzie (Aug. 26).

To be temp. Lts. :—K. D. Zinck (Aug. 1); S. Anderson, C. A. Ewing (Aug. 21).

## TERRITORIAL FORCE, ARMY VETERINARY CORPS.

Sept. 10.

Lt.-Col. W. Plomley is retired under para. 116, T.F. Regna., with permission to retain his rank and to wear the prescribed uniform (Sept. 11).

## OBITUARY.

THOMAS HENRY DALE, M.R.C.V.S., Durban, Natal.  
Graduated, Edin: Dec., 1889.

Mr. Dale died October, 1917.

WILLIAM MALCOLM REID, M.R.C.V.S., Arbutnott,  
Kincardineshire. Edin: May, 1859.

Death occurred 21st August, 1918, at the age of 82.

## Personal.

COCKBURN—SCRASE. At Nottingham, on the 3rd inst., Capt. Robert Bowes Cockburn, A.V.C., eldest son of Mr. Robert Cockburn and Mrs. Cockburn, Eastwood, to Miss Elsie Scrase, eldest daughter of Mr. and Mrs. Scrase, West Bridgford, Nottingham.

## INSURANCE INSPECTION FEES.

Dear Sir,—It gives me very great pleasure to read Messrs. Duckworth & Prince's Scale of Fees for Derbyshire and Staffordshire, in to-day's *Veterinary Record*. I am sure many other V.S. are also pleased.

Will the enclosed list of Gloucestershire V. Surgeons' fees give us all the same pleasure?

### "Insurance Inspection Fees."

Horses under £50 insured value	...	5/-	ea.
" over 50 and under £80	...	7/-	"
" " 80 " 100	...	7/6	"
" " 100 " 110	...	10/6	"

Sixpence per mile, one way.

P.M. Fee, 1 guinea.

1. Any larger sum by arrangement.
2. Every case to stand on its own basis."

There's profit in that 6d. per mile, isn't there?

Yours, etc., W. V. S.

## How to kill an Association.

The following is recommended as the American infallible lethal recipe for this purpose :—

1. Don't come.
2. If you do come, come late.
3. If too wet or too dry, too hot or too cold, don't think of coming.
4. Kick if you are not appointed on a committee, and if you are appointed, never attend a committee meeting.
5. Don't have anything to say when you are called upon.
6. If you do attend a meeting, find fault with the proceedings and the work done by other members.
7. Hold back your dues, or don't pay them at all.
8. Never bring a friend, who you might think might join the Association.
9. Don't do anything more than you can possibly help to further the Association's interests; then when a few take off their coats and do things, howl that the Association is run by a clique.

*Pharmaceutical Journal.*

## Dr. Clement Stephenson's "A.A." Herd.

On the 3rd October the herd owned by the executors of the late Dr. Clement Stephenson will be sold at Baliol College Farm, near Newcastle.

The late Dr. Stephenson held a position all his own for forty years. A brilliant veterinary surgeon, a breeder of rare distinction, and a man of singular personal attractiveness, Dr. Stephenson's remarkable victories at Norwich, York, Birmingham and Smithfield Fat Stock Shows, and his immense enthusiasm were of extraordinary consequence in the Aberdeen-Angus world. His *Luxury* is still accounted a wonder, and very few have seen finer fat show specimens of the breed than Bridesmaid of Benton and Benton Bride. The herd is now in admirable breeding form. Most of the cows are fine milkers, and nearly all are in good season. The doctor's favourite families, the Brides, descended from Lady Craigo, the Lady Idas of the same foundation, Ericas, Jilts, Luxurys, three branches of Prides, Kinochtry Princesses, and Porthlethen Lucys are all there. The younger cows by the champion, Prince of Jesters, make a beautiful show. They have clean polled character, a general air of refinement, and wonderful

quality of bone. As a lot the heifer calves by the old champion and the home-bred Parole of Benton, a son of the well-known prize-winner, Reviver, make a pretty display, and there are promising bull calves in a well-grown group. Regret in connection with the removal of a long-familiar landmark is linked with pleasure in seeing such a grand collection of cattle at the end of the day.—*The North British Agriculturist*.

#### Calcium Carbide.

The Secretary begs to remind members that Calcium Carbide and Dissolved Acetylene for the purpose of head lights in motor cars can only be obtained by permit from the Controller of Non-Ferrous Material Supply.

Applications must be made through the Secretary of Royal College of Veterinary Surgeons, 10 Red Lion Square, W.C. 1, on forms AM2/H.B. The Secretary will be pleased to supply forms on application.

#### Rabies—Order for Devon and Cornwall.

A case of rabies in a dog at Plymouth has been confirmed by the Board of Agriculture and Fisheries. Several other cases that are suspicious have been reported and are now under investigation.

In view of these circumstances and the fact that it is known that in more than one instance persons have been bitten by suspected dogs the Board have made an Order prohibiting the movement of dogs out of the counties of Devon and Cornwall and requiring the control of dogs within a large area of these two counties.

The public are warned that any case in which symptoms suspicious of rabies are observed the police should at once be notified.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1576.

SEPTEMBER 21, 1918.

VOL. XXXI.

## THE COST OF DRUGS.

Veterinary Surgeons complain bitterly of the war prices of drugs, and not without reason. The increased cost of drugs is one of the various causes which justify an increase in veterinary charges; and it is likely to persist for a considerable time. But, if we compare the supply and prices of drugs with those of many other commodities, we shall find that our case might be much worse than it is. It is true that the high price and scarcity of many drugs, including some of the more important ones, is serious. In the case of others—the supply of which is State-controlled, veterinary requirements are being recognised by the Government; and it should not be forgotten that there are not a few most useful agents which remain plentiful in supply and reasonable in price.

There are successful practitioners who, for years past, have systematically followed the custom of always using the cheapest drugs that would meet the needs of the case. Doubtless the saving they effected in the individual case was often very small; but in the long run they accomplished a considerable economy. If it was worth while to follow such a practice in pre-war days, it is surely much more so now. Possibly some even to-day do not realise how many and varied are the possible therapeutic uses of, for instance, so well-known a drug as sodium bicarbonate.

## HODGKIN'S DISEASE OR PSEUDO-LEUKÆMIA.

Several cases in the dog of this interesting though very unsatisfactory condition have lately been recorded. Only one, however, was certainly diagnosed; for the use of the microscope is essential for differential diagnosis. Various diseases, especially leukæmia, malignant growths of the lymphatic glands, and some cases of tuberculosis, may easily be confused clinically with pseudo-leukæmia; and only the microscope can settle the question. Even the positive result of the tuberculin test does not exclude the possibility of a co-existence of leukæmia or pseudo-leukæmia.

No case of recovery from Hodgkin's disease is recorded, and no case likely to be clinically mistaken for it would be expected to recover; and thus Mr. Yates' statement that he has "heard from other practitioners of recoveries," is of some interest. All such cases belong to the class in which, if treatment is attempted at all, it would be well whenever possible to seek a pathologist's aid in establishing the diagnosis at the commencement. If this is not done, the pathologist can only pass judgment upon the unsuccessful cases; while any that may recover must remain unsolved problems.

## REVISION OF FEES.

We print this week a letter from Mr. S. Adams, on the revision of veterinary surgeons' fees in Gloucestershire which emphasizes two points in favour of the line of action taken there and in Derbyshire—that local adaptation is far preferable to a general rate: and secondly, that it is possible to obtain equally good results by more than one method of assessment. Incidentally it is brought out, too, that a fair amount of unanimity is likely to follow a judicious initiative.

A proposal of a similar character at the meeting of the Eastern Counties fell flat. Either the conditions are undesirable, or the initiative—in which the personal element counts so much—is lacking. True the statement is incomplete, in that only the rate of "mileage" is definitely mentioned as not workable. It is said that fees have been "notoriously low there for many years past." Does it necessarily follow that low fees should continue to rule there? Will not the earnings of those counties allow of reasonable fees to their veterinary practitioners? Thirty years ago a good part of agricultural Essex was derelict, and land was let in Suffolk at five shillings an acre for sheep feed: do those conditions exist now? And even if they do, do not present market conditions warrant an increase on the pre-war scale of fees? Finally, it has to be remembered that the public are as willing as ever to rate a man (or a group of men) at his own valuation. Possibly the remark as to low fees was intended to apply particularly to C.C. and Insurance work, but it is not so stated: and if it were, we may call to mind the enthusiastic and persistent efforts of the late Theo. C. Toope, and the fair measure of success which attended them in Kent.

Two other items in our columns this week are worth a passing note. One from the Journal A.V.M.A., is the main part of a resolution passed nearly two years ago, from the Amer. Vet. Med. Association to the Hon. Secretary of War, concerning the depletion of the Horse Stock of the country. It is of interest in that it is an exemplification of the position taken by the Association, and of their initiative on a question with which they are intimately acquainted. It is wholly satisfactory in that it is a distinct movement of the profession to claim its rightful position—to prove its value, and to utilise its accumulated knowledge for the benefit of the State.

Another is a resolution concerning the advertisement of biological products, and read in connection with the recent confiscation of a consignment of these goods, it appears that their government is taking action against this form of swindling.

## TWO CASES IN CHILDREN OF TUBERCULOSIS OF SUPPOSED BOVINE ORIGIN.

By G. GAIR, M.R.C.V.S., Conon Bridge, Ross-shire.

*Case I.* A child, two-and-a-half years old, believed to be affected with epidemic cerebro-spinal-meningitis.

A sample of the cerebro-spinal fluid was obtained by puncture and handed me by the hospital surgeon, with a request to examine the liquid for the diplococcus intracellularis meningitidis. Although I examined the fluid within half-an-hour after its being drawn, no meningococcal infection could be detected. The fluid itself was rather clear, and contained a considerable percentage of lymphocytes.

This lymphocytosis would indicate a tuberculous or poliomyelitis process. A few films of the fluid were therefore made and stained by the Ziehl-Neelsen method, when numerous tubercle bacilli were revealed.

For the purpose of ascertaining the changes in the nuclei of the polymorphonuclear (neutrophil) leucocytes in advanced tuberculosis, I obtained blood films from the child and stained by Leishman's method. A few of these films which I had over were stained by Ziehl-Neelsen method and a number of tubercle bacilli were found: as many as ten might be seen in one field. Several fields showed varying numbers up to four. Great care is required as to "finds" of tubercle bacilli in blood films; there are so many pitfalls, and several reported cases have not borne investigation. Artefacts (particles from stains, distilled water, etc.), may be mistaken for organisms.

The case was one of advanced tuberculosis. The child died a few days afterwards.

The milk supply was obtained from a dairy in the district from which the child came, and in which dairy tuberculous cows were found.

*Note.* Concerning the prevalence of lymphocytes in the cerebro-spinal fluid mentioned above, I have repeated noticed that this result is very indicative of tubercle bacilli, while the presence of polymorphs indicates a meningococcal, streptococcal, or pneumococcal infection. Normally there are only one or two leucocytes per cubic millimetre, but in diseased conditions the number is increased to from fifty to one hundred per cubic millimetre.

This count is easily ascertained by using gentian-violet-tinged three per cent. solution of acetic acid, which is drawn up 0.5 on the pipette. The cerebro-spinal fluid is then sucked up to 11.0. After mixing, make the cell-count with the hæmocytometer. Cerebro-spinal fluid containing blood is not satisfactory for the cell-count, but one can calculate the leucocytes in such blood contents by counting the red corpuscles, and subtracting one leucocyte for every 750 reds.

*Case II.* A child, aged two years and nine months. The history of the infection was as follows:—

The milk supply for the child was obtained from cows which were tested by me half-yearly with tuberculin, and which were always in excellent health.

About mid-March the milk supply from these cows was discontinued through their approaching calving, and the milk from a neighbour's cow was thereafter used. No other milk was given the child for the ensuing ten days when, on visiting the byre, I found the cow had an occasional cough and, on closer examination, that one of the hind quarters was enlarged. On examining the milk from this quarter, I discovered great numbers of tubercle bacilli therein.

I had the milk supply from the animal immediately stopped, and informed the parents of the child that although it only had the milk for ten days, the fact of the milk containing tubercle bacilli in such numbers would certainly cause serious trouble later. I also advised them to notify their medical advisor of the facts.

Three months afterwards the child became decidedly ill and restless. The mesenteric glands became appreciably enlarged, and by December the spinal column was involved. Two Edinburgh specialists diagnosed the case as tuberculosis of bovine origin caused by tuberculous milk and to whom, by request, my report on the case was forwarded.

There is no question of heredity in the case, as all the family were and are in excellent health.

The child is still under medical treatment.

## ARSENICAL POISONING IN THE HORSE WITH PULMONARY COMPLICATIONS.

The condition which we are about to describe is met with in the mining districts of Cornwall, and possibly also in other counties where horses are worked in similar surroundings. It may be assumed that the symptoms are those of an uncommon and apparently undescribed form of arsenical poisoning, and in many respects there are marked deviations from the appearances exhibited when the drug is consumed in toxic doses. The condition in question is in all probability a reflex one, dependent upon irritation of nerve endings, possibly also of the respiratory centres in the medulla, which in most cases have already become impregnated with arsenic.

The horses affected are to be found among those employed in carting stanniferous ores and sand, in the vicinity of tin streaming operations. The majority of the animals which exhibit the symptoms are old and usually somewhat emaciated, and often have spent the greater part of their lives in the same surroundings, have become saturated with arsenic and able to tolerate the drug in the amounts which might be absorbed during the course of their ordinary work. It may here be stated that practically all horses which have been employed for any length of time at particular work in connection with tin-mining and in districts where the soil, forage and water are all more or less contaminated with arsenic, show symptoms of chronic poisoning. This state of chronic arsenicalism is manifested by a dry, staring coat; in a few advanced cases alopecia exists to a marked degree; brick-red dis-

colouration of the visible mucous membranes, and a general appearance of unthriftiness.

Beyond this stage the toxic symptoms seldom progress under ordinary conditions except when, as we shall now show, a relatively enormous dose of arsenic is absorbed on one or more occasions by an animal whose system is already saturated with the drug.

The tin-streams and pools usually contain, in addition to tin ores, large amounts of iron compounds, notably the red-oxide and combinations of iron, arsenic and sulphur (mispickel mundic, etc.), as well as, in some instances, free arsenic and various other mineral compounds.

In all cases of the particular condition we have met with the history has shown that the horses have, within a short period, drunk from the "mundic water." In a few cases it would appear that the same thing has occurred upon other occasions without any ill-effects having been observed, in fact the drivers appear invariably careless of such happenings, and frequently leave their charges standing knee deep in the streams in order to cure "grease." The same disregard of danger is shown by cowkeepers, who dose their cattle with the water in an endeavour to check chronic diarrhoea—a condition not infrequently arising in these localities from ingestion of arsenical fodder—disregard the fact that the proportion of the same metal in the water is frequently exceedingly high.

The fact that horses will voluntarily drink such contaminated water may appear strange until we recollect that cases only occur in animals whose digestions have been already impaired by the continued admission of arsenic to the alimentary canal, and in which the appetite has become depraved. Such horses will frequently drink greedily from the streams if permitted.

The horse becomes suddenly ill. The attitude is one of extreme dejection, the head is held at the level of the knees, the elbows are abducted, and respiration is greatly accelerated. The breathing rapidly grows noisy, and more or less marked spasm of the glottis occurs, which occasions a prolonged snore at each inspiration. The conjunctival mucous membranes are congested, brick-red, and frequently protrude beyond the eyelids. The nasal membrane is also congested and shows the same pronounced tint, whilst the nostrils are widely dilated. The inspiratory effort is somewhat prolonged but the double expiratory movement common in emphysema is lacking.

Auscultation of the thorax reveals a distinct asthmatic condition arising from spasmodic constriction of the bronchi with more or less spasm of the glottis. Fever is usually absent, and the animal exhibits no symptoms indicative of abdominal pain.

It soon becomes evident that the pulmonary vessels are becoming overloaded with blood, and a marked "venous pulse" may be observed. From this time the symptoms may abate, but in the great majority of cases pulmonary congestion ensues. The breathing becomes more distressed, the glottis is evidently constricted to a marked degree and

respiration is distinctly audible at thirty yards. The horse may now fall and die from asphyxia after an illness lasting only a few hours. In many cases, however, the condition persists for one or two hours longer, and œdema of the lungs sets in. Froth collects around the nostrils, a very copious rusty or blood-streaked discharge emerges, and the horse gradually subsides into a state of coma and dies.

In one case, death was preceded by extensive hæmorrhage from the lungs, an indication of the degree of pulmonary congestion present.

Treatment appears useless. The degree of dyspnoea precludes any possibility of administering drenches. Bleeding from the jugular, and the hypodermic administration of stimulants affords no relief. In nearly all cases the condition ends fatally.

At the commencement the symptoms are in most respects identical with those of asthma, and in those cases which have recovered there has been nothing, apart from the history, to distinguish the condition from an ordinary attack of acute spasmodic asthma.

We have never observed typical cases, running the complete course and terminating in death, among horses employed on mine works, unless they have previously been the subjects of chronic arsenical poisoning and have subsequently been known to drink water from the contaminated streams. There is, however, nothing to suggest that similar cases may not arise when the source of the arsenic is other than "mundic water."

Falmouth.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### INFLUENCE OF FRESH AND STERILISED COW'S MILK UPON THE DEVELOPMENT OF NEURITIS IN ANIMALS.

R. B. Gibson and I. Concepción reported some experiments upon this subject in the *Philippine Journal of Science* for 1916. In two chickens, fed daily with 100 c.c. of milk, fresh or submitted to the autoclave, and with 40 grammes of decorticated rice, a slight polyneuritis was produced in the fifth week. Feeding with 200 c.c. of fresh or sterilised milk produced neither polyneuritis nor even any histologically demonstrable commencement of nervous degeneration. These facts prove that milk contains a small quantity of vitamine, which is not destroyed by two hours in the autoclave at 125° C.

Small dogs, fed exclusively upon fresh or sterilised milk, at the end of forty-seven days showed peripheral neuritis with œdema and aphonia, but no scorbutic symptoms. Analogous results were obtained in pigs. In all the cases, alike in animals fed with autoclaved milk and those fed with fresh milk, growth was accomplished. This confirms the observation made upon the chickens, viz., that the anti-neuritic vitamine resists the autoclave.

This vitamine exists in the milk in very small quantity; for if nothing is added to the lactic regi-

men of young dogs and pigs, the animals become bevi-bevic. The anti-neuritic power of milk is so feeble, that in infantile alimentation the regimen should be extended as much as possible. The young of mothers in good bodily condition are probably born with a reserve of vitamins; and this enables them to feed upon milk and grow regularly till a diet more rich in vitamins is available.—(*Revista de Higiene y Sanidad Pecuarias*).

#### SUPRASCAPULAR PARALYSIS FOLLOWING FRACTURE OF THE SCAPULA.

Fröhner records this case in the *Monatsheft für praktische Tierheilkunde*. A horse, after a long period of lameness of the left shoulder, finally presented the symptoms of suprascapular paralysis. The animal died of colic. Post-mortem, Fröhner found the inferior third of the scapula enlarged to double its normal size and covered with irregular osseous vegetations, which completely englobed the suprascapular nerve. This large callus had resulted from the union of a scapular fracture. The left posterior spinatus muscle was very atrophied and degenerated. Fröhner also records an analogous case described by Karnbach.—(*Revista Veterinaria de Espana*).

#### THE TREATMENT OF BROKEN KNEES.

Schwendimann, of Berne, has written an article upon this subject in the *Schweizer Archiv für Tierheilkunde*. He emphasises the depreciation in a horse's value which the scars of broken knees cause. It is the common opinion that wounds of the knee leave in the injured joint a "debility," which tends to cause new falls. Undoubtedly the retraction of the cicatrix impedes the rapid movement of the carpus, and the joint also frequently undergoes chronic peri-articular inflammatory processes and contractions varying in degree.

These wounds are treated on general lines. Sometimes the treatment is difficult on account of dirt in the wound. In that case all dirt, dead tissue, and earth is removed with scissors and forceps, avoiding hæmorrhages and damage to living tissues. The rest may be left to nature; but it is possible to accelerate the reparative process and so obtain a better cicatrization. Moist antiseptics are useful for this purpose. An embrocation, or a sprinkling of the wound with turpentine, give excellent results, accelerating the separation of mortified tissues and causing a healthy granulation. Treatment is more difficult when there is much loss of substance.

Causes which retard recovery are the dryness and rigidity of the lesion from loss of water, the absence of epidermal counter-pressure, the persistence of infection, and the pruritis, with consequent damage to the affected part, which is presented at this stage. The author, therefore, recommends the use of a protective covering for the lesion. It is not essential that such covering should display any specific action; that it protects the part is sufficient. The author names several, including Unna's zinc-gum (glycerinated gelatine with zinc), Schindelka's

varnish (five parts each zinc oxide and ol. ricini with 40 parts collodion, and those substances which produce a dry cuticle of coagulated albumen. Of the latter he especially mentions a 10% solution of nitrate of silver. Immediately after the application of this, a cuticle of albuminate of silver is formed, which becomes black under the influence of light.—(*Revista Veterinaria de Espana*).

W. R. C.

#### EASTERN COUNTIES VETERINARY MEDICAL SOCIETY.

(NATIONAL V.M.A.—SOUTHERN BRANCH).

A meeting was held at the Bell Hotel, Norwich, on Saturday last, the 14th inst. Those present included: Messrs. H. V. Low, President, Norwich; E. Margaron, Swaffham; M. Bray, Docking; J. K. Gooch, Reepham; J. Barr, Acle; A. Holl, jun., New Buckenham; H. Buckingham, Norwich; J. Buckingham, Harleston; and H. P. Standley, Secretary *pro tem.*, Norwich.

Letters expressing inability to attend were received from Messrs. A. Burgon, Haverhill; J. E. Kitchen, London; H. F. Downe, Diss; W. Turtill, Wickham Market; H. Wilkinson, Martham; F. M. Wallis, Halstead; and others.

After discussion it was decided that the next meeting should be held at Norwich, in the Spring, at a date to be fixed later.

Some of the members of the Essex and Suffolk district considered that meetings ought to be held nearer to them, but it was felt that at the present time, with the rail service so disconnected, this was impracticable. On return to normal times, however, the meetings will be held in the different centres, as in the past.

Mr. H. B. NIXON, of Haverhill, was elected a member of the Society.

The officers for the past were re-elected *en bloc*.

It was decided to send donations of £15 15s. from the Society funds—to the Victoria Benevolent Association one of £5 5s.; to the Royal College of Veterinary Surgeons £5 5s.; and to the Farmers' Benevolent Association £5 5s.

A discussion took place on the veterinary fees as put forward in *The Veterinary Record*, Sept. 7th, by Messrs. Duckworth and Prince, of Derby, but it was felt that the mileage of 1/3 for visits could not be charged in the Eastern Counties, on account of the notoriously low fees which have been in existence there for so many years past, and it was pointed out that a good many veterinary surgeons had only been charging from 1/6 to 2/6 a visit of almost any distance.

After the business many interesting cases were brought forward by the members present, and a lively discussion on these took place.

HARRY P. STANDLEY, Secretary, *pro tem.*

#### INSURANCE INSPECTION FEES.

To the Editor of "The Veterinary Record."

Dear Sir,—It is with great reluctance that I feel that I am compelled to reply to the letter of your anonymous correspondent, "W.V.S.," on Insurance Inspection Fees of Gloucestershire Veterinary Surgeons. As the initiator of this movement I desire to state what we have done in this County. In 1916, being personally dissatisfied with the mileage rate as fixed by the Gloucestershire County Council to their Veterinary Inspectors acting under the Contagious Diseases (Animals) Acts, I wrote

to the Clerk of the Council, pointing out to him the various increases, and asking his Council to advance the mileage rate then paid, viz., 1/- per mile (one way). I waited seven months before obtaining a reply to say that his Council had considered the matter and could not advance the rate.

I thereupon communicated with all my fellow Inspectors in this County, suggesting a petition to be signed by all and presented to the Chairman of the Council, asking for a higher rate. I obtained unanimous support, the petition was duly presented and I attended the County Council Meeting in January, 1918, at their request to support it, with the result that we were successful in obtaining a mileage rate of 1/6 per mile (one way). Also an increased fee for Parasitic Mange diagnosis.

The success attending this movement gave me the necessary encouragement to endeavour to increase the rates paid by Insurance Companies. I circularised a number of my colleagues in early 1918, giving them my personal ideas and asking for suggestions. I had in reply many suggestions which showed much thought and consideration. From these replies the enclosed scale\* was drafted, and approved by every Veterinary Surgeon in the County of Gloucester, and by many of their neighbours in the adjoining counties.

I congratulate Messrs. Duckworth and Prince upon their published scale of fees, and I desire to point out to "W.V.S." that Insurance Inspections are not expected to be carried out at once. Seven days may elapse before the return is made. Also that our scale will show approximately the same return per animal per inspection in this County as that obtained by Messrs. Duckworth & Prince.

Upon reference I find last year that the average inspection entailed five miles (one way) and the average value £80 to £100. This, under our scale, would make the fee 10/-. Next year the value should be higher, when the return will be greater. We have adopted for the first time a mileage rate, and hope that such will be recognised generally in future. I think you will agree, Mr. Editor, that we have done something in obtaining 1/6 per mile from the Gloucestershire County Council, and our scale for Insurance examinations, which is open to annual revision, shows an advance of 33½ % for work which is not immediate but can be done at one's convenience, being a start in the right direction.

I may add that the funds of the Royal College of Veterinary Surgeons benefited also, inasmuch that those gentlemen who were not already subscribers promised to become so, and were supplied with the necessary Banker's drafts.

I regret to occupy your space at such length, and I have every confidence that the members of the profession will judge our efforts in the County of Gloucester as honest endeavours in the right direction.

I am, Sir, yours truly,

Dursley, Sept. 17.

A. S. ADAMS.

\*THE LOWEST SCALE of Fees which will be accepted by the Veterinary Surgeons of the County of Gloucester and their immediate neighbours, for Inspections and Reports to Live Stock Insurance Cos. :-

Horses under £50 insured value	...	each	5/-
" over 50 and under £80	...	"	7/-
" " 80	...	"	7/6
" " 100	...	"	10/6

Post-mortem examination, £1 1s.

Sixpence per mile, one way.

1. Any larger sum by arrangement.
2. Every case to stand on its own basis.

### Remounts for U.S. Army.

The following paragraphs are from a letter sent by the American V.M.A. to the Hon. Secretary for War; they seem to indicate a better measure of co-operation than exists in Britain. The intercommunication with Government Departments is a recent innovation with us.

"Already it has become very difficult to secure serviceable horses for the regular army and militia service, and in the south-west it is out of the question to buy the really desirable type, as the amounts offered for the purchase of individual horses are not enough to meet the bids of the buyers of the foreign governments.

"It is the opinion of this association that this situation is already a handicap to our army and could be converted into a serious menace by international complications such as have threatened this country a number of times in the past two years. To meet this situation there are two things which this association would respectfully bring to your attention.

"One suggestion is that the United States Government meet the prices of foreign buyers in purchasing horses. It is not to be expected that owners of horses will sell them to the government at a sacrifice in preference to selling them to foreign buyers at a profit. Not only a regard for the best interests of the country, but good business judgment should indicate that when suitable remounts command increased prices, those prices should be authorised and paid rather than permit the purchase [by the government] of unsuitable and inferior types of animals.

"Another suggestion is that the purchase of mares be authorised. The old objection that they could not be kept owing to the presence of stallions, the property of officers, no longer applies as the use of stallions is not permitted. It is the opinion of the army and militia officers in general that mares are as desirable animals, and polo players regard them as perhaps superior in endurance and perception. All of the foreign armies use mares. A new French contract now being filled, calls for 25,000 horses, of which 20 % to 30 % shall be mares. At Ft. Riley 40 % of the remounts are mares, and in the army polo organisation 60 % of the ponies are mares.

"We have the precedent of the purchase of mares for the Native Cuban Cavalry by Q.-M.-Gen. Luddington during the Spanish-American war on the grounds that these animals would be of more value to them at the close of the war in re-stocking the country with horses. At the close of the present European war, unquestionably many of the mares now leaving this country will be sent to the farms as were the mounts of the Cuban Cavalry and those of the American armies at the close of the Civil War. There could be no objection to this if it were not that the removal of the pick of the American Cavalry horses is already so extreme as to threaten us with serious consequences if our army should need them any time in the next few years. A fresh crop of horses can no more be produced out of hand on demand than can trained soldiers be produced.

### Udder Disease in Dairy Stock.

To the Editor of *The Scottish Farmer*.

Sir,—Mr. Scott points out, in his letter, the seriousness of the disease known technically as contagious mammitis. There is every reason to believe that this disease could be eradicated if the matter were taken up in the proper manner. The first step would be a proper bacteriological study. It is highly probable that an efficient preventive vaccine could be prepared which would immunise healthy cows wherever there is a possibility of their becoming infected, in the same way as human beings can be immunised by the injection of

typhoid vaccine against typhoid. The matter would have to be taken up by the local authorities in the infected counties. A proper scheme could be easily worked out. It would provide for compulsory notification to the county veterinary inspector through the police, the isolation and detention of the affected animal. Provided an efficient vaccine could be prepared and a suitable method of vaccination devised, the farmer would be given the opportunity to have all the remaining healthy cows vaccinated. It might be found worth while to vaccinate healthy herds where the disease has not yet appeared. A better study of this disease might show that an effective serum can be prepared which would arrest an attack if injected into an animal very early in the course of the disease. This would be expensive and could only be done for valuable animals. I give only this rough sketch to show the need for scientific investigation into this as well as other diseases.

Yours, etc., S. H. GAIGER, F.R.C.V.S.  
Glasgow Vety. Coll. Prof. of Pathology.

### ARMY VETERINARY SERVICE

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Sept. 12.

REGULAR FORCES. ARMY VETERINARY CORPS.

To be temp. Lt. :—J. McL. Galloway (June 29).

Sept. 13.

Capt. H. Peele (T.F.), to be actg. Maj. while holding the appt. of Dep. Asst. Dir. of Vety. Servs. (July 28).

Sept. 17.

Maj. (Bt. Lt.-Col.) A. Olver, C.M.G., F.R.C.V.S., to be actg. Col. whilst holding the appt. of Dep. Dir. of Vety. Servs. (Sept. 18).

Temp. Capt. to be actg. Maj. :—R. Clunas (June 18).

Temp. Capt. H. Barnard relinquishes his commn. on account of ill-health, and is granted the hon. rank of Capt. (Sept. 18).

Sept. 18.

To be temp. Lts. :—N. M. Crawford, G. E. Lay, J. T. Melanson, E. S. Notting, I. Robson (Aug. 7); F. W. Buckle (Aug. 8); W. F. Fennelly, A. J. Kelly (Sept. 1).

TERRITORIAL FORCE, ARMY VETERINARY CORPS.

Sept. 13.

Capt. (actg. Maj.) P. J. Simpson to be Maj. (May 27, 1916).

### A Lesson.

One does not learn all his lessons in college. Here is one I might have learned but did not. It may be of help to some other practitioner.

I was called about 8 p.m. to see an aged horse that had suddenly gone "dead lame" while at pasture. A young man who had been hunting started to drive the horse to the barn. The old horse appeared to be frightened at the boy's gun, galloped a short distance, stopped suddenly and refused to move except on three legs. The owner, an old German, took a lantern and went with me to the pasture. An examination revealed a comminuted fracture of the os suffraginis of the left front leg. The broken pieces would simply "squash" on pressure. It was a hopeless case as the horse was at least twenty years old, so I told the owner I could do nothing for the horse and that he should be put out of his suffering. The old man dropped his lantern and throwing his arms about the horse's neck cried like a child. On my way back to the barn the old man, between sobs, offered to pay me for my visit, but as he was in rather poor circumstances and this was his only horse I had pity for him and made no charge.

After I had left he sent eight miles for a non-graduate to see the case. This man confirmed my diagnosis and

prognosis and took his fee. I did not like it very well and the next time I met Herman on the road I told him so. He said, "Vell, you didn't charge me nothings, so I takes dat money for the odder feller."—D.V.S., in *Jour. A.M.V.A.*

### Plea for French Colonial Veterinary Service.

The confirmation of rinderpest in French Western Africa calls attention anew to the insufficiency of the Veterinary Services in our Colonies.

It is not possible by the hap-hazard recruiting of civil practitioners, or by making use of military veterinary officers liable to frequent changes of station, to constitute a *personnel* capable of carrying on the difficult tasks imposed upon them.

It is both necessary and urgent to effect for the Veterinary Service what has already been done for the Medical Service, that is—to create a corps of colonial veterinarians specially prepared by a suitable course of training. It is not less indispensable that these services should possess an autonomy and a status which would enable them to fulfil their mission effectively.

The knowledge acquired of the tropical diseases of animals is already considerable. We may be sure that it will increase rapidly under the hands of men trained in the methods of investigation. For the moment we need only recall what has been effected by our allies, the English, in India and in South Africa.

In any case, the European nations will need to husband their resources for long years to come, and to obtain all possible help from their colonies. To develop and conserve the live stock of our colonies is to prepare for the future.—*Revue générale de Médecine Vétérinaire*.

### Misleading advertisements.

The following was adopted by the Committee of the American V.M.A. a couple of years ago. There is less need for it on this side, perhaps, but it is a perfectly justifiable position.

The Special Committee on Advertisements of Veterinary Remedies recommends that the following resolution be adopted, by this association :—

*Resolved:* That misleading claims for biological products should not be tolerated by this association, and any official of any firm or corporation who is a member of this association and allows such claims to be made, the same shall be sufficient reason for rejection or expulsion from this association; and this association should accept the federal regulations governing biological products as a standard of application."

### Personal.

#### MILITARY MEDAL.

Corporal (A/Sergt.) S. V. GOLLEDGE, of "D" Compy., Duke of Wellington's West Riding Regt., eldest son of Mr. J. Golledge, M.R.C.V.S., of Brookfield, Trowbridge, has been decorated with the Military Medal at the hands of Lord Cavan, Commander-in-Chief of British Forces in Italy.

The accompanying certificate reads :—"During the action this N.C.O. was responsible for the blocking of the trenches on the flank and in carrying out his duties showed great skill and coolness. He rendered valuable assistance at the end of the operations in getting wounded away from the enemy lines, personally carrying back a N.C.O. Throughout the raid and in previous reconnoitring his conduct was beyond all praise."

Sergt. Golledge joined the A.V.C. in 1915, and was transferred to the Infantry in 1917.—*The Wiltshire Times*, Sept. 14.

[Before joining up, Sergt. Golledge was a student at the Royal Veterinary College.]

# SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

S. Chambers, Kirkheaton	£1	1	0
W. St. J. F. Macartney, Capt. A.V.C.	1	1	0
J. M. Tate, Pretoria	1	1	0
Previously acknowledged	995	12	11
	£998	15	11

# "PATENT MEDICINES."

Sir,—The above is a misnomer. If these preparations were patented the formula would have to be disclosed to the public. The proprietors have no legal right to use the word patent. It is used as a blind, and to increase the mystification surrounding these expensive and, in most cases, useless nostrums. They do not sell on their merits, but by expensive advertising, and glib tongues of travelling agents, who make farmers believe that they will drag any case from the brink of the grave.

Here is the composition of one or two:—

"Red Drink." Mag. sulph., a little pulv. gent., and zing., and Bol. G.S. to colour.

"Hoose Mixture." Ol. turp., Ol. lini., a "whiff" of Eth. sulph., colour.

A largely advertised liquid blister:—Tinct. canth., Tinct. caps., Ol. croton, Sp. V., colour and scent.

In order to combat the sales of these preparations we must put up a united front, and act as one man, in condemning and opposing their use in every case.

Two years ago I issued circulars among farmers in this district pointing out that they had to pay for all the expensive advertising, fancy labels, cases, boxes, rail carriage, and swell travellers, in return for articles of very doubtful utility, and certainly not worth the high prices charged for them. These circulars diminished the sale to a large extent, and I know some of their "toffs" had some nasty questions put to them "next time round."

I think this is a case in which the Board of Agriculture could render valuable assistance to the farmer, by analysing, and publishing the formula of these nostrums. The mystery would then disappear, and with that the sales—to vanishing point.

Farm stock is too valuable at present, and should not be the receptacle for "Night, Sun and Humbug's" cure-all, because "I happened to have it in the house."

The firms who sell these preparations do not contribute anything to the State in the way of stamp duty, and at the present time are using drugs which might, with advantage to the nation, be directed into more useful channels.

R. M. MALLOCH, M.R.C.V.S.

Kirkby Stephen, Sept. 14.

# A PROLIFIC MOTHER.

Recently a retriever bitch gave birth to eighteen puppies; fortunately for the food supply, only seven of them survived. The owner is Mr. Gardiner, Fearon Street, Greenwich.

Blackheath, Sept. 14.

HENRY DYER.

At the annual honey market of the Co. Wexford Beekeepers' Association, held at Enniscorthy, the takings were estimated at £3000; one small farmer received £350 for his supply.

# SUPPLY OF VETERINARY SURGEONS FOR THE ARMY.

To the Editor.

Sir,—"Joseph Bindle" is right. I know a gentleman who joined up at Potchefstroom as a private in the S.A.M.C., under the assurance that when he got to England he would be given his commission in the A.V.C. He duly arrived in England—during the bitterly cold wintry weather—and was very shortly packed off to France. From here he was sent home about a year ago as a stretcher case. He has several times applied for his commission, but is still a "Tommy." Like "Joseph Bindle's" case, this gentleman had sat for his D.V.H., and, incidentally, nearly saved the life of a horse (how valuable I cannot say, but worth at least £85 at that time) in France. The animal belonged to his own unit, had fallen into a shell hole and somehow or other had severed a radial artery. Our "Tommy's" C.O., knowing him to be a qualified veterinary surgeon, called him to the case, and "Tommy" proposed castrating the animal, cutting down on, and picking up and ligaturing the artery. But REGULATIONS (Capital letters, please) would not allow a "Tommy" to do this, so a V.O. (distant about 10 miles) was sent for, but—the horse had bled to death before this latter gentleman arrived! At least £85 plus the price of another to replace him thrown away.

No doubt you have heard about Sister Susan sewing shirts for soldiers? Here is a parody on the S.A.M.C.: Silly S.A.M.C.'s scraping scabs off soldiers. Just imagine! A fully qualified and thoroughly efficient veterinary surgeon—I know him well—scraping scabs off soldiers!

There is a great demand for Veterinary Officers! In the parlance of our friend, the Gaul—*Je ne pense pas!* It would be interesting to know how many V.O.'s are at the present time languishing in Woolwich and Aldershot waiting to go somewhere.

By-the-way. What will become of the vast quantity of unqualified men? I personally know such an one (a captain) who has been at least once, and I believe twice, prosecuted by the Royal College—who have been granted commissions? Will they be presented free, gratis, and for nothing with a diploma by our President and Council, or be given such high credentials by the Big Bugs of our Veterinary Service as to enable them to settle down in opposition to Veterinary Surgeons (both "Tommies" and "Officers"), and

SILVER BADGE?

Sept. 5.

# Scientific and Industrial Glass Ware.

In a lecture by Prof. Sir Herbert Jackson, delivered at the British Scientific Products Exhibition on Sept. 6, the lecturer disposed of the fallacy that until the war we did not manufacture optical glass. Seventy years ago British lenses were famous, and now 95 per cent. of what was used in this country was made here. Specimens which he had seen produced by an English firm during the past six months were finer than any he had seen from any other part of the world. We are now making finer glass for the laboratory, miner's lamp glasses, thermometer-glass, opal glass, etc., than any ever imported from Germany. Forty-one million vacuum fruit jars have already been produced by our makers and distributed. Sir Herbert has every confidence that after the war England will rapidly regain and maintain her old position in the glass industry.

# Horses in low condition.

At Woodbridge, on Thursday, 12th inst., before the Right Hon. J. W. Lowther, M.P., chairman, and Mr. H. F. Harwood, Sidney Abbott, carman, 8 Handford Road, Ipswich, was charged with cruelty to a horse at Grundisburgh, and Alfred Hughes, foreman horsekeeper, 1 Crown Street, Ipswich, was charged with causing the horse to be ill-treated. Mr. Bernard Pretty defended.

P. C. Gray stated that when a pair of horses in a van belonging to Messrs. Talbot & Co. drove up to the Dog

Inn, at Grundisburgh, the near side bay mare fell exhausted, and examination revealed a number of wounds. On a later date Abbott, who was in charge of the horses, told Inspector Sheriff, R.S.P.C.A., that he was out for the purpose of collecting empties. The mare had some wounds on the shoulder, but it was thought they had sufficiently recovered to admit of one journey; he had called the attention of the foreman to the condition of the horse before he started. Hughes, on being interviewed by Inspector Sheriff, said he sent two horses to do what as a rule one had to do. The horses were on rations, and all were in a low condition; they were willing to buy them food if they could get it.

Hughes, giving evidence, said he had had charge of horses for twenty-three years, and had now twenty in his care. He had not been able to get sufficient and proper food for them; he bought the best he could get. He had won several prizes and certificates for the care of horses at the Felixstowe and Ipswich horse parades.

Mr. William James Browning, M.R.C.V.S., said Hughes was a very superior horse manager; he had known him for many years, and he had always taken great care of the horses under his care.

Abbott deposed that there were only 35 dozen empty bottles in the van.

The Chairman said the Bench decided to convict under the section of the Act which stated that if any person did any act causing unnecessary suffering they were liable. Hughes would be fined £1 and Abbott 10s.

The fines were paid, but at the conclusion of the Court Mr. Hughes asked that it might be returned in order that he might appeal against the decision.—*East Anglian Daily Times*.

#### Rabies in Devonshire.

The Board of Agriculture and Fisheries wish to inform Veterinary Surgeons that many dogs, including dogs taken to sea-side resorts by their owners, have been removed from Devon and Cornwall before the Order, which prohibited movement of dogs from these counties was issued on September 9th, 1918.

The Board therefore suggest that Veterinary Surgeons take this fact into consideration when being consulted about dogs which have recently been in either of these counties, or dogs which have been in contact with such dogs.

Dogs suspected of being affected with rabies should be placed in security and reported to the Police under the Rabies Order.

Veterinary Inspectors of Local Authorities who suspect from the symptoms, history and post-mortem finding that a dog has died, or been slaughtered on account of rabies, should sever the neck where it joins the shoulders.

The head and neck should be wrapped in a cloth which has been soaked in a solution of corrosive sublimate (1-1000), packed in a strong box marked urgent and sent by passenger train to the Laboratory of the Board of Agriculture and Fisheries, New Haw, Weybridge, Surrey.

For purposes of identification a note giving the names and addresses of the sender and owner and a brief history of the case should be enclosed in the box in such a manner that it avoids contact with the damp wrapping.

There should be no delay in making the post-mortem examination or dispatching the head and neck to the laboratory.

No. 1578.

OCTOBER 5, 1918.

VOL. XXXI.

## SCHEDULED DISEASE.

Last month two events occurred which forcibly remind us of our constant danger from contagious animal disease abroad. Foot-and-mouth disease appeared in East Sussex; and a case of rabies was detected at Plymouth.

We have become familiar with these incursions of foot-and-mouth disease; and there is, fortunately, no reason to fear that we shall be less successful in dealing with the present one than with many others in the past. The outbreak of rabies may seem more of a novelty to the public; but it will not surprise veterinarians. Only one case of canine rabies has appeared in England since 1902; and that one developed in the security of quarantine, thereby justifying our quarantine regulations. Throughout that long period of immunity the disease prevailed more or less in France and other Continental countries, and only our rigid quarantining policy has preserved us from it. Soon after the war broke out it increased greatly in France, as was inevitable; and the subsequent developments in cross-channel intercommunication must have afforded temptations and facilities for dog-smuggling. Doubtless the present outbreak has originated in some transgression of the regulations; and we can only hope that any such that can be brought home to the perpetrators will receive the utmost severity the law permits. The maximum legal penalty for this offence is much too light, considering the issues involved. If all detected infringements are dealt with sharply, and the old preventive measures strictly applied whenever necessary, we need not fear a re-establishment of rabies here. Already there are cases confirmed in six dogs and one other animal, and other outbreaks may follow for some time to come—perhaps far away from Plymouth. At present, all practitioners should be on the alert against the possibility of rabies, especially in view of its diagnostic difficulties in its early stages.

Our indigenous scheduled diseases remain much as they were in the early summer. Glanders still shows a slight increase upon last year, and parasitic mange a very considerable one, both probably due to war conditions alone. In neither case is there any cause for anxiety. The figures of anthrax and swine fever remain satisfactory, and those of sheep-scab fairly so. On the whole, we may heartily congratulate the Board of Agriculture veterinarians upon their record of work against scheduled disease through the last four difficult years, and upon the position they can show us to-day. We must not forget that the dangers from scheduled disease are likely to become more serious soon after the war ends than they have been at any time in its duration.

## CHRONIC POISONING OF CATTLE WITH RAGWORT (*Senecio Jacobaea*).

*History.* Seven young Shorthorn cattle—three heifers and four bullocks, about 16 months old, all in fine blooming condition, were, in spring, turned out into a grazing pasture—second year lay. As the season advanced the field was practically covered with large growths of ragwort. In the second week in July, when they were in full flower, they were cut down with the mowing machine and left on the ground. About a month after new and vigorous growths were seen, and at the same time one of the heifers was noticed ailing. She was brought indoors when my son saw her: there was nothing much to be noticed, except she was very languid, had lost her bloom and her fine rounded appearance; temperature normal, no diarrhoea, in fact the faeces were costive—much too stiff for an animal on grass. The only symptom of note was that the visible mucous membrane, inside of the ears, round the anus and vulva were of a deep yellow colour. Owing to the extreme heat of the weather, my son considered the case to be one of bilious fever, and small repeated doses of sulphate of soda, and a few vegetable tonics were given. At present the heifer is doing better, but not up to the mark. The other six were now observed to have lost their bloom, were tucked up in the flank and not doing well.

About the end of August they were removed to a fine flush meadow foggage. On the 16th September, after a very stormy day and night, one of the bullocks was found dead in the field. The case was notified to the police, when I was called. I may here state that this was the first time I had seen the animals.

After certifying that the case was not anthrax, I made a post mortem of the bullock. On opening into the abdomen, a quantity of brownish-yellow fluid was observed; the peritoneal covering of the abdominal viscera had a pale, wasted appearance; the liver was of a slaty blue colour, very hard, (cirrhotic) highly mottled, and gritty on cutting; the gall bladder was about twice the normal size and distended with a yellowish-green watery bile; the lining showed several small dark spots studded throughout. The first, second and third compartments of the stomach appeared normal, except that the cuticular lining stripped off readily in some parts, but the fourth or true stomach was very highly congested, and the internal folds were of a dark bluish-pink colour and much thickened by a submucous exudation. The small intestine also showed several congested patches in different parts; and the urinary bladder was distended with dark yellow urine.

From the condition of the lining of the fourth stomach I concluded that the bullock had been eating some irritant vegetable poison. On investigating the case the cutting of the ragwort was brought out, but whether the animals had eaten the cut, dried plants or the new growths I was unable to find out. I may state that the cut plants grew very fast, and are now again in full flower.

On referring to Lander's Veterinary Toxicology—on Poisonous Plants, pages 224, 225, and H. C. Long's "Plants Poisonous to Live Stock," pages 44, 45, I was convinced that the ragwort was the cause of the trouble. The post-mortem of the bullock agreed exactly with the conditions described by both gentlemen. I may, however, state that there was not, nor has there been, any diarrhoea in these animals. It appears that it is known in Canada as Pictou disease—hepatic cirrhosis. Also in New Zealand it causes considerable disease in sheep; whilst in South Africa, cirrhosis of the liver in cattle—Molteno disease, is also attributed to the eating of one of the plants—*Senecio latifolius*.

I think I am right in stating that it is erroneously considered in the British Isles that ragwort is not injurious to stock; in fact, in order to prevent these growths it is a common practice to put sheep on to the pastures in early spring, just when the ragwort makes its appearance above the ground in the form of a small bulb, before it breaks into leaf. The sheep eat these with much relish and take no harm, but as the plant grows, neither horse, cow, nor sheep seem to touch it. Is it not possible that the eating of ragwort may be the cause of some of the cases of chronic diarrhoea that carries off so many young stocks rising two years old?

Referring to this case, the remaining six stirks have been removed from the rich fog and put on to some old laid grazing land, and the feed supplemented by a little crushed oats and bran with a little salt every morning, and a small foddering of old hay at night. They all seem to be going on nicely, but are far from what they should have been.

Perhaps some of the readers of *The Record* have met with similar cases, and it would be pleasing to have their view. I have related the case as I found it.

Aspatia.

HY. THOMPSON, M.R.C.V.S.

[Poisoning by *Senecio Jacobaea* was referred to in our issues of Sept. 1 and 8, 1917, pp. 89-91, and 105, in connection with cases which had occurred in Ireland. Earlier it was noted by Mr. J. A. Gilruth. We reprint below the essentials of the note on the cases in Ireland for comparison. So far we have not seen any other note of its occurrence: it is probable that cases have occurred, but have been wrongly diagnosed or left unnoted.]

"Poisoning under natural conditions is a slow process, that is to say, an animal does not receive, and could not eat enough of the weed at one meal to cause acute poisoning. The poisoning is cumulative in its action; and with continuous doses the amount of poison which becomes available is sufficient in time to cause very serious symptoms, which often end in death."

"It would appear also that animals which have received a toxic amount of ragwort over a certain period

may seem healthy at the time when feeding on the material is discontinued, may nevertheless develop active symptoms of poisoning, and die at a later period. Thus, in the cases which have been investigated, some of the animals did not show definite symptoms until twelve days or more after the feeding with ragwort has been discontinued.

"In the early stages the animals have the appearance of being hide-bound. Later they walk with a staggering gait, some appearing to be partially blind or heedless of where they go. Later they become very excitable, and will charge at anyone who approaches them. In some there may be diarrhoea, but usually constipation is so marked that it causes violent straining. The pulse is weak and rapid, but the temperature remains normal.

"When death takes place in the earlier stages of poisoning the principal lesions found are inflammation of the mucous membrane of the bowel. The omentum is dropsical. Small hæmorrhages are present under the mucous membrane of the bowel and in the pericardium. In acute cases the liver is firmer than normal and yellow in colour, the yellow colour apparently arising from fatty degeneration of the liver cells. In chronic cases there is cirrhosis of the liver, and in such cases the abdominal cavity contains fluid. This is not unlike what is seen in some animals affected with fluke disease. The lungs are congested.

"There is no cure, and prevention resolves itself into removing the ragwort from the forage or eradicating it from the pastures."

#### PUNCTURED NAVICULAR BURSA WITH NECROSIS OF THE APONEUROSIS.

In reporting these cases, I think the great factor of success was the use of an autogenous vaccine.

The two cases ran a similar course; both had been treated by owners with poultices until the lameness became excessive; when I was called in there was a free discharge of synovia and pus from the wound at side of frog.

Treatment consisted of thinning the sole and frog, and opening the puncture as much as possible. The foot was daily bathed in Jeyes', a carefully applied antiseptic dressing was put on with a leather boot over all. Excessive granulations were kept down with caustic dressing,  $\text{CuSO}_4$ , when necessary.

A swab was sent for autogenous vaccine, and the vaccine given for six consecutive days. There was distinct reaction, lameness and discharge being increased. Two or three days after the finish of the vaccine a portion of the necrotic aponeurosis about the size of a shilling was found in the dressing. After this, discharge gradually became less and complete healing quickly took place.

By the use of caustic and the knife the puncture in sole was kept open, which gave a fairly free exit to the portion of the necrotic tendon.

I do not know if practitioners in this country carry out the classical operation of resection: if so, I have never seen a case reported. It would be interesting to have the experiences of anyone who has done this operation for the cure of necrosis of the aponeurosis.

G. E.

## ABSTRACTS FROM FOREIGN JOURNALS.

## THE PHYSICO-PHYSIOLOGICAL TREATMENT OF TRAUMATIC ABDOMINAL HERNIA IN THE HORSE.

G. Mullie, in the *Recueil de Médecine Vétérinaire* for 1917, relates three observations upon cases of hernia of this class. The results of his treatment enable him to conclude that certain abdominal hernias may be treated easily and efficaciously by the elevation of the posterior third of the body and the observation of a reduced diet. This treatment is especially applicable to cases of traumatic hernia with posterior localisation and with a hernial ring of narrow diameter.

The position, declining from behind forwards, which is given to the horse during the treatment, by its mechanical effects permits the intestinal mass to be directed and drawn towards the antero-inferior region of the abdomen. These effects may cause the spontaneous reduction of the herniated mass, and the consequent cicatrization of the abdominal traumatism. The concentration of the diet, by diminishing the volume of the gastrointestinal mass, is a powerful aid in obtaining the desired result.—(*Revista de Higiene y Sanidad Pecuarías*).

[This treatment seems well worth trial in suitable cases, especially if there is a doubt whether operation is economically advisable.—*Transl.*]

## A TEST OF THE PRESENCE OF DEATH.

The difficulty of ascertaining death with certainty before signs of putrefaction appear is well-known; and, though the subject is not so important in veterinary work as in human medicine, it is not without moment to veterinarians. Dr. Lecha Marzo has discovered a very simple method, based upon the acidity which the parenchymas, blood, and lachrymal secretion acquire in the dead subject. The test is made by placing a strip of neutral or blue litmus paper under the eyelids for some moments. In the dead subject the paper becomes red; in the living it is blue.—(*Revista de Higiene y Sanidad Veterinaria*).  
W. R. C.

## A REPORT UPON AN OUTBREAK OF FOWL TYPHOID.\*

By WALTER J. TAYLOR, Assistant Professor of Veterinary Science, College of Agriculture, University of California.

Although fowl typhoid has been recognised as such in but few instances in the United States, we believe that in many cases of so-called fowl cholera, fowl typhoid was the real cause of loss and was not recognised because this disease had not received the attention accorded to fowl cholera.

Attention was first called to this disease in 1894 by Theobald Smith who found it to be present in Rhode Island. The following year Moore studied the same disease in Virginia, and the first graphic account of an organism as a causative factor coupled with a description of the symptoms, morbid anatomy and the specific organism was presented by him at that time. He isolated and described an organism which he named

*Bacterium sanguinarium*, and which he showed to be the causative factor. He suggested the name "Infectious Leukemia" for the disease. Further investigation, however, has shown that the disease is not a true leukemia, but rather a leucocytosis brought about by the infecting organism. Curtice studied an outbreak of the disease in Rhode Island in 1902 and gave it the name of "Fowl typhoid." This latter nomenclature seems to be more applicable and was accepted by Moore in a later publication. In 1913 Pfeiler and Rehse described the organism anew under the name of *B. typhi gallinarum alcalifaciens*.

A brief history of the outbreak which led to the investigation of the disease in California is as follows:—In the spring of 1912 a poultry raiser in San Francisco lost several fowls rather suddenly from a disease which seemed to occur sporadically, but which did not spread to other members of the flock. The birds of the flock were kept in small lots of 12 to 25 each. Seven or eight mature hens succumbed to the first attack. A post-mortem revealed yolk of eggs in various stages of development and all appeared to be ruptured. Considerable yolk substance was also present in the abdominal cavities of the birds. The owner informed the writer that he attributed the cause of death to "broken eggs," and thought nothing further about it. The carcasses were buried in one of the yards where the dirt was loose and no further trouble occurred during the year.

At the time our attention was first called to the disease the owner gave the following history:—

"On May 5, 1913, I had 70 hens and pullets one year old and over, 6 breeding males, and 260 chicks of various ages. The birds commenced to die about the 7th or 8th of May, 1913. The first to succumb were laying hens which had been allowed to run outside the yard and had access to the burial place of those which died last year. The birds did not seem to become affected in any regular sequence, but came down in bunches of 6 to 10 at a time and at intervals of several days. The yolk condition noted in those which died last spring was present, also a peculiar pale condition of the kidneys which led me to suspect poisoning. The birds having been given quite a quantity of water cress for green food, I attributed this as the cause of death, because the contents of the intestines had a more or less greenish tinge.

"An interval of two weeks elapsed before any more birds showed symptoms, and these were observed more closely. The first symptom noticed was the drowsy or sleepy appearance of the affected birds. Soon after, the droppings became soft and of a yellowish colour, occasionally streaked with green. They were especially green from one male bird. The birds showed a disposition to stay on the roost, unwilling to move about, sleepy most of the time, head down into the ruff or hanging pendent. They would be sick for 5 to 10 days then die. Both males and females were affected.

"Post-mortem examination showed kidneys to be from clay to terra cotta coloured, sometimes streaked with red showing capillary congestion and the ureters were filled with a semi-solidified urine. Quantities of free yolk were present in the abdominal cavity of the hens and occasionally the mesentery would be dotted with dark spots. Still believing the birds to be dying from some form of poisoning especially affecting the kidneys, I sent the backs containing the kidneys from several birds to the chemical laboratory for analysis, but no evidence of poison was found."

It was at this time that the writer was asked to make an investigation of the disease. On visiting the place, July 25th, we found about twenty-five birds consisting of Rhode Island Reds, Barred Rocks, and White and Brown Leghorns, both male and female. Nine Rhode Island Red hens were sick at the time. The runs and houses were dry and free from any decaying matter.

\* Presented at the meeting of the A.V.M.A. Section on Sanitary Science and Police, Oakland, Cal., Sept., 1915.

The sanitary conditions were far above the average. The roosts and dropping boards were clean and the dropping board had been freshly dusted. The nine affected hens were housed by themselves and showed the same symptoms as those already described. They had been affected three or four days at the time we saw them. The most striking symptom observed at that time was extreme sleepiness and a tendency to remain on the roost. Diarrhoea was present in about half of the cases. No young birds were seen, as they had been sold for slaughter in an attempt to reduce the economic loss as far as possible. Only a few of the younger birds had died. They appeared to be less susceptible to the disease than the mature fowls.

In the young chicks, however, the disease seemed to be very rapidly fatal. A large percentage of several hatches died in from a few days to several weeks of age, all showing the same symptoms observed in the older birds, and upon post-mortem no pronounced lesions were found, save a peculiar paleness of the intestines and kidneys.

Disinfection of the pens was advised, also permanganate of potash in the drinking water. Instructions were left to send the first dead bird to us for examination.

*Post-mortem notes.* July 31. Adult Rhode Island Red hen in good condition. Died on twelfth day after symptoms appeared. Comb and skin about head pale and anæmic. Visible mucous membranes pale. Peritoneum pale, and showed a yellowish exudate. Intestines pale, contents normal, oviduct somewhat congested. Numerous egg yolks present, varying in size from one to two millimetres in diameter. Some of the larger yolks ruptured. Liver slightly enlarged, very friable, dark red in colour with darker red markings occurring in streaks. Indistinct areas of necrosis one to two millimetres in diameter, colour of clay evidently under liver capsule. Kidneys swollen, of a clay colour with a few narrow red streaks on the surface. Spleen slightly enlarged, lungs normal, heart muscle pale with a peculiar irregular mottling of a light gray colour. Blood of heart all contained in auricles very thin and watery.

Cultures were planted on slant agar from liver, oviduct and heart blood. In 24 hours the cultures from the liver and heart blood showed a growth of a short rod-shaped organism, 1 to 2 microns in length with rounded ends. It grew singly or in pairs. It took the aniline stains but feebly showing a dark periphery and lighter centre. It did not take the polar stain shown by certain species of the *Pasteurella* group. Cultures from oviduct mixed.

(To be concluded.)

#### MIDLAND COUNTIES VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A.—NORTHERN BRANCH.]

The quarterly meeting was held at the Grand Hotel' Birmingham, on Wednesday, Aug. 29. Mr. J. Malcolm' President, occupied the chair; and the other members present were:—Messrs. J. J. Burchnall, J. W. Conchie, J. Cormack, Gascoyne, F. L. Gooch, J. Martin, A. Over, T. Slipper, F. V. Stewart, R. C. Trigger; Capt. J. T. Whyte; Messrs. S. M. Woodward, J. Young, and H. J. Dawes, Hon. Sec.

Apologies for unavoidable absence were received from the following:—Messrs. F. B. O. Taylor, T. Thomson, S. J. Marriott, C. Parsons, R. L. Phillips, T. J. Brain, P. C. Woolston, W. E. Ison, G. F. Prickett, C. E. Dayus, R. Hughes, T. Ludlow, A. B. Forsyth, R. Over, and others.

The minutes of the previous meeting were read and confirmed.

#### The late Mr F. H. Gibbings.

The Hon. SEC. said it seemed lately to be their inevitable lot to mourn the loss of one or other of their members. Since they last met, Mr. F. H. Gibbings had passed away, and he was sure they would like to place on record their deep sense of the loss which the Association and the profession generally had thereby sustained. Mr. Gibbings had not only filled the office of President, but had regularly attended the meetings and won the admiration of the members by the good sense and sound judgment he at all times displayed when participating in their discussions. He moved that a letter of sympathy be sent in the name of the Association to the family.

Mr. BURCHNALL, in seconding, said that he and Mr. Gibbings were fellow students and passed out of College the same year. He was a warm hearted friend, and the news of his death came to them all as a sad blow.

The motion was carried in silence.

#### REPORT OF COUNCIL.

The Council sat immediately prior to this meeting. The report contained a recommendation that the arrangements for the next quarterly meeting be left in the hands of the President and Hon. Sec. The question of fees was raised and it was decided to refer it to the general meeting. [The report was adopted.]

#### THE VETERINARY TRIBUNAL.

The PRESIDENT referred to the compliment recently paid to the Hon. Sec. in appointing him a member of the Military Tribunal which had been set up to hear applications for exemption by veterinary surgeons. No man, he said, was better qualified to act in that capacity than Mr. Dawes, on whose sense of absolute fairness they might implicitly rely.

Mr. DAWES thanked the President for his remarks. He said he felt it his duty to accept the honour, because his long official connection with this Association had brought him into personal contact with so many veterinary surgeons.

#### THE REVISION OF FEES.

The Hon. SEC. reported the result of correspondence between himself and the National Veterinary Association on the subject of increasing their fees in view of the higher cost of living, the extra cost of drugs and transport, etc. The Association invited all affiliated bodies to discuss this question and to communicate their views to them, with the object of some joint action being taken, if possible, by the whole profession.

Mr. TRIGGER showed the meeting a circular which had been placed in his hands, signed by the practitioners in a particular district, in which an increased scale of charges for visits, operations, inspections, medicine, etc., had been decided on. The new scale was duly specified.

Capt. Whyte, Messrs. Woodward, Gooch, Conchie, Young, Martin, Gascoyne, Cormack, Stewart, Trigger, and the President and Hon. Secretary took part in the discussion.

Eventually, Mr. Gooch proposed that a report of this discussion be sent to the Council of the Royal College of Veterinary Surgeons, and to the National Veterinary Association with an expression of this Association's opinion that it is desirable in the present circumstances that the fees of veterinary surgeons should be substantially raised, and that a note to this effect be inserted in the leading agricultural papers.

This was seconded by Mr. Cormack, and carried unanimously.

#### CASE NOTES.

Capt. WHYTE mentioned an unusual case of a breech presentation in a heifer. He raised the hind quarters by means of a block and pulley and ropes attached above the hocks. It was then not difficult to put the

fœtus back, but it required considerable force to bring it away—the force of four men. He then found on examination a big rupture in the superior surface of the vagina. He told the farmer it was a hopeless case; and was surprised to hear afterwards that she had made a good recovery. He attributed that to the fact that the after-birth came away immediately after the calf; otherwise there must have been septic infection.

He mentioned two remarkable cases of animal intelligence. A blind mare lost her foal, which had got into a thicket, and she came close up to the house and neighed, thus drawing the owner's attention to her trouble.

He also saw a heifer which was in the habit of pushing her tongue through the finger hole in the door, and raising the latch to let herself into the shed. The other cows used to make way for her to come up and do this.

Capt. Whyte also related some of his recent experiences in France. He was at one time in charge of an infectious ward and a case was handed over to him as one of strangles. It made no progress until one day he removed a piece of shell, and a quick recovery followed.

On another occasion he had to treat a very vicious horse suffering from grease. It could not be attended to in the ordinary way, and no one dare go near it. He put it into stocks, clipped the hair off, washed with soft soap and a solution of calcium sulphide, and afterwards applied a solution of chloride of zinc. He afterwards sprayed the hind legs twice a day, and it made a complete recovery. He came across many cases of grease, and the veterinary sergeant told him the animals did better in the sunshine, where the sun got on the legs all day. He tried that with good results, the sun apparently having a drying effect on the legs.

At one time the weather in France was so hot as to be hardly endurable. One afternoon he was sent for to another Company to see a horse that was very ill. It was delirious, staggering about, and unable to stand. He diagnosed it as a case of heat stroke. The temperature was so high that it burst his thermometer, which registered 100 degrees. He borrowed a bigger thermometer, inserted it and watched it, and the mercury went up to the very top. The animal died 20 minutes later, and when he put his hand into its mouth it was like putting it into very hot water. There were other cases the same afternoon, but not so bad, of course. An hour afterwards there was a thunderstorm; he had the animals tied out in the rain, and next morning they were all right.

He also met with a great number of cases of spavin in France. He tried the Dickerhoff treatment. He used the hot iron and burnt a hole in the centre of the spavin, varying the depth according to the size of the size of the spavin, and made a few small holes round about. He did not blister, but applied a little antiseptic ointment, and except for one mule, every animal recovered.

The Hon. Sec. said he had a very curious case now under treatment. There was a severe thunderstorm, and the groom saw nothing wrong with the patient at the time (a valuable cart horse of high courage), but next morning he noticed it was dull. He (Mr. Dawes) was sent for, and when he got there he found the horse was deaf and blind and very stiff in its movements, and no action of its bowels for a couple of days. A little aloes was given and the bowels responded, and after a fortnight a peculiar thing happened. It looked as if the horse was suffering from mange, from the appearance of its coat. The hair began to come off, and in three weeks or a month the whole of the body was as bald as the back of one's hand. Mr. Malcolm saw the horse and could corroborate what he (Mr. Dawes) said. In a fortnight the hair began to grow, and the animal now had a very good coat. It could also see and hear all right, and it had now been turned out with every prospect of

a good recovery. It was extremely tender in the region of the poll, which seemed to be slightly swollen, though there were no marks of injury or of the animal having been struck by lightning.

He mentioned a case of a mare foaling in which, when he arrived the foal's head and neck were protruding through the anus and the feet through the vagina. It looked a hopeless mess. He pushed the head back again and delivered the foal, which was alive and did well. There was an immense rupture. He was surprised to find that the mare did very well for about two months. At the end of that period, the attendant found her dead. Whether it was a result of the rupture he had been unable to ascertain. The remarkable feature of the case was that the mare should have lived at all in the circumstances.

Mr. CONCHIE said a client once asked him to take a cleansing from a cow which had calved two days before. The cleansing came away, and a week later the owner asked him to look at the cow again. She did not get any better, and he afterwards put his hand in to feel if any of the cleansing was left, and all he found was a great rupture in the uterus.

On another occasion a client sent for him to see a mare which had a very bad humour. The leg was swollen in two or three places. Some pus worked through the vagina. A fortnight later, what appeared to be a core had come between the stifle and the hock. Examination proved that it was a piece of bone (which he now showed to the meeting). The mare had done some chain work and it was supposed that through carelessness on the part of the lad in charge she had injured herself in some way.

Mr. TRIGGER said he had found in parturition the most frequent cause of tearing was the breech presentation. The cow died, to the veterinary surgeon's surprise, after she had apparently gone on well. That made him wonder, and he sought the cause. He found that the bone of the hock cut like a knife, going straight through. He had proved that by blood-stained markings on both hocks. That accounted for many ruptures. He had only had two or three recoveries when there was rupture of the womb. With regard to raising the cow's hind quarters, he regarded it as a risky experiment, although, of course, it might be used in moderation.

On the subject of animal intelligence, Mr. Trigger mentioned the case of a pit horse which, the moment "loose it" was called (the signal to finish work in the pit) would not do another stroke of work. Yet during ordinary hours a better working horse never lived.

Mr. OVER produced for inspection the mummified fœtus of a calf in exceedingly small compass.

Mr. GOOCH said he had in his possession two fœtuses of a similar type which were in the cow for a year and eleven months. He thought the cases of rupture that recovered were those where the rupture was in the superior portion of the uterus.

Last Thursday, continued Mr. Gooch, he was sent for to a valuable Shire colt, for which the owner has refused 165 guineas. He came to the conclusion that it was suffering from impaction through eating new oats. The horse was not tympanitic, but was full of pain. He treated the animal and was sent for again in the evening. To his astonishment he noticed what appeared to be a displacement of the double colon. He was tempted to puncture, but did not do so. Later in the evening he punctured, the animal being much worse, but the enormous pressure in the rectum was not relieved. He punctured from the rectum and was able to manipulate the bowel. He thought there was a half twist of the double colon. The moment the gas was out the colon resumed its proper position and the whole of the flatulence went out. Next morning there was distension of

the left side. He punctured again. The pulse was over 100 and the temperature 102. There was no action of the bowels, and on Saturday he injected eserine subcutaneously. On Sunday morning he removed six or seven pieces of very hard fæces. Although there was a rise of temperature, he believed the animal was going to recover. He used a long trocar. He was of opinion they commonly used too small a trocar and canula. If he had a similar case again he should not hesitate to puncture at the rectum with the same trocar.

Mr. MARTIN mentioned the case of a farmer who bought a heifer and walked it home several miles. He (the speaker) was sent for, as there was something the matter with the animal, and he noticed tympany. The animal died, and the *post-mortem* revealed a twisted uterus. There were gallons and gallons of fluid which had accumulated there as a result of the injury. With regard to breech presentations, he never hesitated to sling either mares or cows.

Mr. Young produced for inspection a cystic tape-worm found in a Belgian hare.

Mr. SLIPPER said that last spring he had two unusual cases in dairy cows which were seen by Mr. Malcolm. There were swellings in the throat, neck, withers, and fore legs. One animal died and the other was killed. There was no injury that he could see in any way.

This spring he had three cases, in a haulier's stable, of paralysis of the pharynx. They could not swallow, and just starved to death. He was wondering whether the food had anything to do with it. They were having mouldy hay and a large quantity of vinegar grains, which were not fresh, but had been allowed to lay in a lump in the stable.

He also mentioned a case of twisted uterus in a mare. He cast the mare, rolled her, when the twist was reduced, the foal came away and the mare made a good recovery.

Mr. WOODWARD produced the skull of a fox terrier which had suffered for some time from absorption of the bone, the bone being replaced by a sort of cartilage. He had three cases altogether, all in the same district. He had never seen such cases before.

The PRESIDENT said he thought they might congratulate themselves upon a very profitable exchange of experience. With regard to the use of the spray in the treatment of grease, referred to by Capt. Whyte, he thought it was also now commonly used in the treatment of mange. It could be left to an intelligent stableman to undertake, and he had himself found it very efficacious. With regard to twist he had seen more cases than he wanted to see, and it was generally associated with impaction of the stomach. Limiting the food to the proper quantity was, he thought, a good preventive, and one which could not be dwelt upon too strongly. Since he had given those instructions he had reduced the number of cases to a minimum. The cases mentioned by Mr. Slipper were certainly very interesting, but he could not explain them.

#### A.V.C. COMFORTS FUND.

The HON. SEC. said a copy of the report of the Army Veterinary Fund had been received, together with the reminder that the good work was still being carried on. He thought the Association would be quite willing to subscribe again, and he suggested that last year's subscription of five guineas be renewed.

Mr. TRIGGER thought that after advocating a 25% increase on their own fees they ought to make a similar increase in the case of this subscription. He knew the Fund had done a great amount of real good and was very much appreciated.

Several members spoke to the same effect, and all warmly commended the Fund.

The HON. SEC. said he was quite willing that a sub-

scription of seven guineas be made by the Association to the Fund.

This was seconded in several places, and carried unanimously.

The members then adjourned for tea before dispersing.

H. J. DAWES, F.R.C.V.S., Hon. Sec.

#### THE EDUCATIONAL VALUE OF ENGLISH.

The note on "The value of the study of English" is taken from a review by E. H. Starling, F.R.S., Prof. of Physiology, University College, London, on the Report of the Committee on "The position of Natural Science in Education," under the presidency of Sir. J. J. Thomson, F.R.S.

"Once we have rationalised our educational aims, natural science will fall into its proper place. But this place is not first in the educational hierarchy. It is universally accepted that the 'three R's'—reading, writing, and arithmetic—must form the groundwork of elementary education. We do not recognise in this country that training in language and expression is a necessary precedent and accompaniment of all other education, and that we need a training in the use of our own language not inferior to that given in French in the schools of our Allies. Without appreciation of language clearness of thought is impossible, and literary form is one of the best guarantees of good reasoning. But no training in mere language is sufficient or profitable unless the mind is supplied with material to work upon.

A proper training in language as the expression and symbol of things, the relations of things, the relations of men, and finally of the feelings of men, while promoting accuracy of thought and judgment, will minimise the hypnotic influence exercised on the inarticulate by meaningless catchwords and party cries.

The very fullness and perfection of the English language make it, perhaps, the most difficult to master, even by those who are English by birth and upbringing. Most of us have felt how the defect in our school training in English, or its absolute default, continually impedes the expression of our ideas, and prevents any rise out of the ruts of the commonplace. Even a scientific article could and should be beautiful in its fitness of expression, and it will not lose in its usefulness if it pleases the ear as well as satisfies the reason. The majority of our generation have not advanced in the writing of English beyond the stage which, under any proper system of education, ought to be attained by an intelligent boy of 14. But if by this age the boy has learnt not only to express himself with form and propriety, but had also studied the structure and origin of his language and the meaning of the roots, especially Latin and Greek, of the words which he uses, he could begin at 14 the study of Latin as something already half familiar to him, and in a couple of years could attain such a knowledge of this language as is at present reached only by a small minority after six or eight years of stupefying drudgery. Better still if, as Mr. W. Johnson advised in Sir Ray Lankester's volume of essays, he had learnt French with his English. Each language would teach appreciation of and help in the study of the other, and the boy would be ready to play some part in the inter-Allied activities which will replace, we hope, for the next hundred years the present reign of destruction, terror and pain.

The value of the study of English is strongly emphasised in the Committee's report, which also points out the advantage from a practical standpoint of a knowledge of modern languages. But the report is chiefly and properly concerned, not with the reform of education as a whole, but with the changes necessary to give to the study of natural sciences its proper importance in the general scheme of instruction."—*The Lancet*, Sept. 14.

## ARMY VETERINARY SERVICE

War Office, Sept. 24.

The King has been pleased to approve of the following awards in recognition of gallantry and devotion to duty in the field:—

## THE MILITARY CROSS.

\* \* \* \* \*

Capt. MICHAEL FRANCIS O'SULLIVAN, A.V.C., S.R.—Seeing hostile shelling near the neighbouring wagon lines, he rode over to assist, and in spite of heavy shelling got all horses to safety in the coolest manner. Next night he gave great assistance in getting all ammunition away from a dump under constant shell fire. On more than one occasion subsequently he volunteered for duties of a hazardous nature.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Sept. 27.

## REGULAR FORCES. ARMY VETERINARY CORPS.

Temp. Hon. Capt. to be temp. Capt.:—E. C. Winter, F.R.C.V.S. (Sept. 6).

Oct. 1.

To be actg. Maj.:—Capt. R. C. G. Thwaytes, whilst holding the appt. of Asst. Dir. of Vety. Servs. (Oct. 5, 1917); Temp. Capt. G. Sutton, F.R.C.V.S. (Dec. 25, '17).

Temp. Lt. to be temp. Capt.:—V. Franklin (Aug. 14).

Oct. 2.

Maj. G. P. Knott to be actg. Lt.-Col. while holding the appt. of Asst. Dir. of Vety. Servs. (June 16, 1917). (Substituted for notification in *Gazette*, Nov. 19, 1917).

Temp. Lt. to be temp. Capt.:—H. V. Dier.

## SPECIAL RESERVE OF OFFICERS.

Oct. 3.

Lt. to be Capt.:—J. W. Beaumont (Sept. 18).

India Office, Oct. 1.

The King has approved the promotion of the following Officer of the Indian Defence Force:—

Vet. Lt. to be temp. Vet. Maj.:—K. Hewlett (Oct. 2, '17).

## Acorns as a Cattle Food.

The following are from a column in *Farm and Home*, over the initials J. P. D. Some details are given as to quantities and methods which may be of use in these days of food substitutes: they are a distinct advance on the usual generalities on the subject.

There is a difference in foraging for acorns and receiving them clean and together in a feed. In the fields intervals occur between the finding and eating, so that there is time for mastication, and there is the exercise and fresh open air to be taken into account. Acorns should not be fed to swine in confinement or to sheep in folds. A sow with, say, nine or ten suckers six weeks old might receive a couple of gallons a day in two servings, the acorns being scattered on the straw; older pigs in proportion. A pint a day for each sheep thrown on the pasture, or in troughs if they are on roots, would be a good ration. Fowls and ducks do well on them, and half-a-pint in two servings would be sufficient without other food, when they are at liberty: half the quantity supplemented with other food would be enough if they are confined. Acorns are said to cause the eggs

to become dark and discoloured. I do not consider it necessary to kibble them, although at first it might be necessary to crack a few until the taste for them is acquired. My hens eat them whole; but they have a free run, and their eggs have not been affected.

As the collected acorns are brought in they should be shot on the floor, under cover, spread to a depth of about six inches, and allowed to remain some days, until they "spear." When the shoots appear they should be spread out quite thinly on a dry floor where there is a draught, the barn floor is generally a suitable place, and be turned over from time to time, until dry. This really amounts to malting, and greatly improves the acorns. They may be thrown into a big heap when dry, and will keep till summer. Acorns must not be heaped up when first collected, or they will heat and mould.

## Grading for slaughter—charge dismissed.

At Newcastle Police Court, on Tuesday, 1st inst., George Storey Moffatt, farmer, Field House, Acklington, was charged with having sent into Newcastle for sale a heifer, which was to his knowledge diseased and unfit for human food on August 20.

Mr. Frank Kirby, from the Town Hall, who prosecuted, said the animal was slaughtered, and found to be in an advanced stage of tuberculosis. The carcass was condemned by a magistrate.

Inspector Parker admitted, in cross-examination, that instructions had been issued by the Ministry of Food that manifestly diseased animals might be placed in Grade IV and sent to a Government slaughter-house.

Mr. T. Lisle Maughan, on behalf of Mr. Moffatt, said his client had only done what other farmers had done in this and other counties. They had been pressed by the Ministry of Food to exercise all economy in the way of foodstuffs, and to see that nothing was wasted. It was a well-known fact that diseased animals had a value to the country in respect of offal, etc. What he did with his eyes open; there was no attempt at concealment. He did not subscribe to the view that this animal was an obviously diseased animal.

Defendant said he owned something like 300 cattle, and sometimes he had doubtful animals. This was one, and he felt that the best thing to do was to send it to the Government slaughter-house. It was never in his mind that any animal that he thought was not fit for food should be sent away to be used for food. He had only acted according to instructions as issued by the authorities.

The Bench dismissed the case.—*Evening Chronicle*.

## Utilisation of Plum-stones for Oil in Germany.

Examination of the stones of plums, cherries, peaches, and apricots gave the following results:—Air-dry stones in plums, 4.1 per cent.; in cherries, 7.7; kernels in plum-stones, 12.6 per cent.; in cherry-stones, 22.9; in peach-stones, 5.7; in apricot-stones, 29.2; oil in plum-kernels, 37.38 per cent.; proteids, 23.78; in cherry-kernels, 38.71 and 28.01; in peach-kernels, 45.45 and 26.01; in apricot-51.43 and 28.36. Yield of oil from plum-stones, 3 to 4.3 per cent.; from cherry-stones, 4 per cent. Germany possesses 21 million cherry trees and 69 million plum trees, and the utilisation of the stones should therefore pay well. The stones can be cracked in a mill and the kernels separated by a solution of magnesium chloride or other salt of specific gravity, about 1.15, in which the kernels float. Plum-kernel oil will keep for years; cherry-kernel oil becomes slightly rancid.—K. Alpers (*Pharm. Ztg.*, vol. 63, p. 354, *ex Pharmaceutical Jnl.*)

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

J. G. Cattell, I.C.V.D., Karachi, India	£1	1	0
William Fawdington, York	1	1	0
Walter Gardner, Colmonell	2	2	0
W. H. James, D.S.O., Maj. A.V.C.	1	1	0
C. J. R. Lawrence, Capt. A.V.C.	1	1	0
Harold Leeney, Capt. A.V.C.	1	1	0
H. P. Standley, Norwich	1	1	0
William White, Birmingham	1	1	0
Eastern Counties Vety. Med. Assocn.	5	5	0

Previously acknowledged 1006 2 11

£1020 16 11

## THE R.C.V.S. LIBRARY.

Dear Sir,—Your leader on the above subject is very timely. Has not your tale of Rivolta a moral in it which, being extracted, amounts to the stressing of the French motto—"aide toi et le ciel t'aidera"?

There may be other more important and urgent affairs than the welfare of the R.C.V.S. Library, but the ignorance in the profession concerning it must be appalling. How many of our members know what volumes are in it or how to obtain a sight of them? When was a library list ever published? Of course, we shall be told that there isn't enough money to publish one. If there is not, the natural corollary is to ask the profession for the money. I venture to write that it will be forth-

coming if this is done; and if it is not, then the library ought to close its doors and sell out. A real live profession will have a real live library—with liberal rules and regulations.—Yours faithfully,

G. MAYALL, M.R.C.V.S.

## CAMEL FEEDING EXPERIMENTS.

A correspondent writes us emphasising the fact that the experiments quoted (*V.R.*, Aug. 24, pp. 61, 62,) were carried out on camels which were suffering from Surra, and are therefore not reliable. This was pointed out in two places in the report, but possibly this reminder is not unnecessary.

## PATENT MEDICINES.

"By Royal appointment."

Registered Trade Mark—

"Disease has found its master."

I live in a small country town, and on each Market Day a representative of the above firm arrives—his first business is to visit all the hotels and public houses and distribute in the most conspicuous places the enclosed literature, not forgetting to place a nice blotting-pad on the writing table, with all the advertisements stamped across.

I can only say that if we have not a Veterinary Surgeon in the profession who is capable of making up a little stock medicine for the Royal Stables and Royal Homesteads the sooner we shut down the Royal Veterinary College the better.

"A COUNTRY PRACTITIONER."

## DISEASES OF ANIMALS ACTS 1894 TO 1914, SUMMARY OF RETURNS.

## THE COUNCIL MEETING.

The proceedings in Council last week were full of solid business; and the report shows that the war has added heavily to the work of our representatives.

Some of the business related to preparations for the after-war period, which, in view of the present position, are perhaps the more important. Among these, if adopted, the recommendations for financial assistance to students may do much to re-inforce the supply of young graduates. Some special exemptions from examinations are also made, the effect of which will be in the same direction. Efforts for the release of students now serving are still going on, and, it is to be hoped, on all counts, may prove successful.

The financial position is as pressing as ever; and the Treasurer's few words upon it, with his estimate of the annual requirements of the College, put the matter squarely in front of us all. We have still much to do, if an adverse balance at the end of the year is to be averted.

As usual—and we regret to have to use the adverbial expression—the Councilmen were too few to act upon the recommendations of the Registration Committee. This repeated delay in Registration work is not creditable.

The report of the Sub-Committee upon the South African Veterinary Surgeons Bill is important. In some directions the Sub-Committee offers valuable suggestions, as, for instance the desirability of the imposition of a registration fee, the position of South African students now attending British Colleges, and the period allowed for our members to give notice who desire registration in South Africa. The question of the South African registration of our members in the future is much more difficult and serious. Clearly, our Council cannot promise to recognise any diploma that may become recognised in South Africa; and the matter is pre-eminently one for adjustment. The suggestion advanced by the Sub-Committee seems a sensible solution of the difficulty.

The General purposes Committee dealt with the letter from the Midland Counties V.M.A. on the necessity of raising the scale of professional fees. It is a matter over which the Council can have no direct control, but they have supported the action of the practitioners as far as they were able by an instruction to the Secretary to reply "that this Committee concurs in the opinion expressed by the Midland Counties Veterinary Medical Association," and the report was subsequently adopted by the Council.

Lastly, it is gratifying to note the award of the Steel Medal to Dr. Griffith Evans, and to read the

accompanying tribute by Maj.-Gen. Blenkinsop. Dr. Evans made his momentous discovery of the first pathogenic trypanosome so far back as 1880; but, though no one has ever disputed his priority, he has received singularly little recognition for work the value of which has long been universally acknowledged. The Steel Medal is all that the Council has to give for such work; it was first awarded in 1897, and it is almost incomprehensible that it should have taken the Council 21 years, and an award by another body—recently announced—to acknowledge the value of this piece of independent research. All members will endorse the award, and join in congratulating the long-retired veteran upon it.

## THE VETERINARY TRIBUNAL.

The first meeting was held on Wednesday, 2nd. A brief report will be found at p. 121. These meetings are open to the public, in common with those of similar bodies. The next will be held on Friday next, the 18th, at the Royal College of Veterinary Surgeons, opening at 2.30 p.m., not as stated at p. 121.

## PROPRIETARY REMEDIES.

A correspondent this week refers to this perpetual sore in another phase—the practice of some men to follow the lines of the advertising firms in the matter of flamboyant and lying labels. It is obvious that without the government stamp, the term "Patent" is misapplied. It is also obvious that the claim to cure a variety of diseases in different animals is an impossible one, and that the sale under these pretences is a fraud and the perpetrator a swindler. The term "quack" is far too loose a definition where serious issues are at stake. It seems more fitting to a stage comedy than to actual life, since it carries a certain tolerant contempt of the individual rather than the condemnation of a cruel deceit.

That some proprietary remedies have proved a distinct benefit is unquestionable—probably no better example can be quoted than Dr. Collis Browne's "Chlorodyne." And no exception can be taken to legitimate profits on such productions.

The practice of using flaring labels, in imitation of manufacturers of specious preparations of foods, medicines, condiments, etc., is not to be commended. They are examples of two arts—advertisement, and lying: and except amongst illiterate folk, they are calculated to lessen that confidence and esteem in which the practitioner should be held by his clients.

## ABSTRACTS FROM FOREIGN JOURNALS.

## OVINE CYSTICERCOSIS.

Ransom published an important article upon this subject in *The Journal of Agricultural Research* for 1913. For nearly half-a-century ovine measles was considered as a scientific curiosity rather than as a parasitic affection capable of causing real disadvantages. Authors upon food inspection have attached only the slightest importance to it. It is an error, however, to believe that the affection is rare; for it is much more common than porcine cysticercosis, which is a disease almost unknown in the United States. When ovine cysticercosis has been carefully sought for, it has been found in a proportion of 2 per cent. In 1912, it was found in 20,000 sheep. It need not be said that if more systematic researches were undertaken, the proportion would augment considerably.

At first it was believed that this parasite of ovines was *C. cellulosa*. When the disease was discovered in America, researches were made upon it, and the conclusion was quickly reached that the parasite is not *C. cellulosa*, despite its resemblances to it, but really the larval form of a tapeworm of the dog, to which Ransom gives the name *Taenia ovis*. The question, therefore, becomes much less important from the point of view of meat inspection; but it is not at all negligible, for the flesh may be depreciated or rendered unsaleable by the abundance and size of the cysticerci.

At first a diagnostic error was made with regard to specimens sent to Washington. From this it followed that, of 4,537 sheep slaughtered at Seattle, 79 were seized in the belief that they were affected with *C. cellulosa*. Similarly, 224 sheep were condemned at Chicago. The error quickly became apparent; for it was inconceivable that the *C. cellulosa*, which is so rare in the pig in the United States, only amounting to a dozen cases a year in hundreds of thousands of pigs slaughtered, should prevail to such an extent in sheep. The truth was elicited by experiments upon seven dogs. Five of these ingested ovine cysticerci; and the other two ingested the *C. tenuicollis*. All the dogs, before ingesting the parasites, received castor oil; and their faeces were examined. In this way the new tapeworm was differentiated.

As there is no transmission to man, the inspection need not be too severe. Where the infestation is only slight, seizure of the affected regions is sufficient; but if the cysticerci are in excessive numbers, rendering the flesh repulsive, total seizure is necessary.

The parasite especially affects the inter-muscular connective tissue. It is found frequently in the heart, the diaphragm, the masticatory muscles, and the tongue. It may be found also in the lungs, the walls of the oesophagus and stomach, and perhaps very exceptionally in the kidneys and liver.

The cysticerci are usually in a condition of degeneration at the end of three months.

It is possible for the parasites to escape the most attentive inspectors; but the disadvantage from this is very slight. Too severe regulations, order-

ing the destruction of all affected carcasses, would mean an enormous economic loss. Careful search may reveal from 1% to 5% of animals affected.

The prophylaxis comprises destruction of carcasses and the treatment of dogs with anthelmintics. The taenia in the dog produces eggs about two months after infestation. Treatment of the dogs every two months is therefore indicated; though that may appear excessive.—(*L'Hygiene de la Viande et du Lait*).

(Neumann, in his *Parasites et Maladies Parasitaires du Chien et du Chat*, published in 1914, mentions this *Taenia ovis* of the dog as having been obtained by Ransom in 1913. He states that it is a species allied to *Taenia marginata*, but gives no detailed description of it. He adds that the ovine cysticercosis which it produces, though common in the United States, is rather rare in Europe.—*Transl.*)

## Royal College of Veterinary Surgeons.

### QUARTERLY MEETING OF COUNCIL.

A Quarterly Meeting of the Council was held at 10 Red Lion Square, London, W.C., on Friday, 4th Oct. Mr. F. W. GARNETT, C.B.E., J.P., President, occupied the Chair; and the following were present: Maj.-Gen. L. J. Blenkinsop, D.S.O., Maj.-Gen. Thomson, C.B., Messrs. Banham, Bradley, Carter, Clarkson, Coleman, Gaiger, Lawson; Sir John M'Fadyean; Messrs. Mulvey, Price, Share-Jones, Slocock; Sir Stewart Stockman; Mr. Wharam; Mr. G. Thatcher, Solicitor; and Mr. Fred Bullock, Secretary.

The minutes of the last meeting and of the special meeting, which had been printed and circulated, were taken as read and confirmed.

It was announced that apologies regretting their inability to attend the meeting had been received from Messrs. Abson, Barrett, Brittlebank, Dunstan, Howard, McKinna, Sumner, Trigger, and Wilson.

*Obituary.* The SECRETARY read the obituary list.

**Dr. Clement Stephenson.**

Mr. MULVEY: Mr. President and Gentlemen,—Amongst the names which have just been read out is that of a gentleman who occupied a seat on this Council some few years ago—Dr. Clement Stephenson. He held a unique position in the veterinary profession, and he was a notable man in the North of England and the surrounding counties. He did good work for the profession for many years; he raised himself by force of character to the very highest position; and in his own immediate district he was called upon on numberless occasions to consult with his fellows. So highly was he esteemed that the University of Durham conferred upon him the degree of Doctor of Science. He was esteemed by all who knew him; he lived to a great age, and he has gone to his rest full of years and honours. I beg to move that a vote of condolence with his relatives be passed. (Hear, hear).

Sir JOHN M'FADYEAN: Mr. President and Gentlemen,—Mr. Mulvey has so admirably expressed what I am sure are our common feelings with regard to Dr. Stephenson's death that it is scarcely necessary to say anything further. Nevertheless, as an old friend and a very sincere admirer of the late Dr. Stephenson, I should like to be allowed to add a few words. He had attained such a great age, and latterly suffered so sadly from the burden of his years, that it would be affectation to pro-

less regret of his death; nevertheless it is very fitting that we should add a tribute of respect to his memory, and give expression to our appreciation of the great work which he accomplished during his life. Dr. Stephenson was a man of extraordinarily strong personality. No one could be brought into contact with him without being impressed with his great ability, his extraordinary energy and thoroughness, and his uprightness; and to all these qualities he added a charm of manner, a kindheartedness and a power of sympathy that endeared him to all those who were privileged to be his friends. Last, but not least, he was a great lover of his profession, and the evidence of that is found in the handsome bequests which he has left, a large proportion of his fortune being devoted to the interests of this profession. We ought to be glad to think that this will serve to perpetuate his name and his memory in the veterinary profession. All in all, we may say that he was a man of whom the veterinary profession had good cause to be proud. (Hear, hear). May his example serve as an inspiration to the younger members of the profession. (Hear, hear).

The resolution was carried in silence, all present up-standing.

#### ADMISSIONS TO MEMBERSHIP.

The SECRETARY announced that since the previous quarterly meeting the following gentlemen had been admitted members of the College:—

##### London.

Mr. H. R. Allen  
G. Barnett  
R. W. Down  
C. W. Heane  
T. H. Jones  
H. H. Leach  
J. McCunn  
D. E. MacRae  
K. S. Simpson  
W. A. Williams

##### Edinburgh.

Mr. R. L. Creery  
J. McAllan  
J. Judge  
H. F. Downie  
J. K. Irvine  
J. R. Rider

##### Glasgow.

Mr. A. L. Robertson

##### Dublin.

Mr. J. T. Alcock  
W. F. Fennelly  
T. C. Hall  
A. J. Kelly  
S. Anderson  
C. A. Ewing  
T. FitzPatrick  
T. J. Hurley  
T. Kelleher  
W. E. Little  
A. J. McCutcheon  
B. S. Parkin  
W. L. Smyth  
D. P. White  
W. Frazer

#### FINANCE COMMITTEE.

Mr. LAWSON read the following report of a meeting of the Finance Committee held on the 4th October:—

*Chairman.* It was resolved: That Mr. Lawson be appointed Chairman of the Committee for the ensuing year.

The Treasurer submitted his financial statement for the quarter showing an adverse balance of £6 4s. 9d., and liabilities amounting to £86 7s. 5d.

It was resolved: That the Treasurer's statement be approved, and that he be ordered to pay the liabilities shown, together with cheques required for ensuing quarter and monthly salaries, also electric lighting, Corporation duty and telephone charges.

*Office Furniture.* The Treasurer reported that in order to provide for the increased work of the office he had purchased a desk and a typewriter, at a total cost of £16 2s. 6d.

It was resolved: That the action of the Treasurer be approved.

*Bonus to Secretary.* It was resolved to recommend that a bonus of £50 be paid to the Secretary and Registrar as an honorarium for extra work.

The PRESIDENT: I expect the Treasurer would like to say something on the report of the Finance Committee.

Mr. MULVEY: All I can say is on the old topic—money. We still want money to carry on. Everyone knows the increased work that is being done in this office, and in order to carry on that work it is necessary to find the means. I may say at once that I consider the response, which now amounts to over £1000, that has been given by the veterinary profession to the appeal is an excellent one. Still, we cannot stop there if we are to carry on. Our expenses may be counted as somewhere about £1500 a year, and I do want to impress upon those members who have not already subscribed to come forward with subscriptions. I do not know that I need add more, except that I want very heartily to support the proposal to give Mr. Bullock a bonus of £50. Mr. Bullock has done and is doing, a very great amount of work more than is really recognised by the profession. The work of the Tribunal, for instance, that has been put upon his shoulders entails innumerable enquiries. The details of every case have to be looked up, and the reason for the application for exemption dealt with. All this entails work, and I hope that the Council will unanimously agree to the suggestion of the Finance Committee that a bonus of £50 be accorded to him.

Mr. LAWSON: I beg to move that the report of the Finance Committee be received and adopted.

Maj.-Gen. THOMSON seconded the motion, which was carried unanimously.

#### REGISTRATION COMMITTEE.

The SECRETARY read the report of a meeting held on the 3rd October, which stated that it was resolved that the President be appointed to the chair.

Mr. G. N. TOMLINSON, Member of the College, was summoned to appear on a charge of conduct disgraceful in a professional respect, namely, drunkenness when in H.M. Service, and that he was convicted of drunkenness by a General Court-Martial, and in consequence dismissed the Service. The Solicitor stated that Mr. Tomlinson had written that he did not intend to enter any defence or to attend the meeting. The Solicitor read the official record of the Court-Martial held April 3rd, 1917, from which it appeared that he was charged with: (1) Drunkenness, (2) Drunkenness, (3) An act to the prejudice of good order and military discipline; and pleaded guilty to (1) and (2), but not guilty to (3). The finding was not guilty of (3), and the sentence to be dismissed from H.M. Service. The Committee find the charges proved.

The SECRETARY reported that he had received no explanation from a member from whom an explanation had been required, and he was instructed to call upon the member to attend the next meeting of the Committee to show cause why his name should not be removed from the Register.

A report of the finding of a Court-Martial held on another member while serving as an officer in the Army Veterinary Corps was submitted, and it was resolved that the member be called upon to appear at the next meeting of the Committee to show cause why his name should not be removed from the Register.

It was resolved that a prosecution be instituted in the case of a non-member using the title.

Six other cases were considered by the Committee, in two of which it was resolved that there was no case, while the other cases were adjourned for further enquiries.

On the motion of Mr. Clarkson, seconded by Mr. Lawson, the report was unanimously adopted.

The PRESIDENT: I am sorry that we have not a quorum at the present meeting to carry into effect the adoption of the report. I hope that at the next meeting there will be a quorum present.

Dr. BRADLEY: I beg to move that the seal of the

College be affixed to the prosecutions ordered in the report.

Mr. CLARKSON seconded the motion, which was carried unanimously.

#### EXAMINATION COMMITTEE.

Mr. MULVEY read the following report of a meeting held on October 3rd:—

It was resolved: That Mr. W. J. Mulvey be re-appointed Chairman of this Committee for the ensuing year.

The reports of the Local Secretaries, Chairmen of the Board of Examiners and Delegates on the examinations held in July were read and approved.

It was resolved: That the examination fees paid by the following students who were unable to take their examination in July owing to illness be held over until the December examinations:—H. O'Leary, Michael Murphy, Wallace Anderson, R. Gregg, John Norris, J. Heffernan.

*Assistance to veterinary students after the war.* The following report was received from the Sub-Committee appointed to consider what assistance, if any, will be required by veterinary students after the war:—

Assistance will probably be required for two classes of students.

1. Registered veterinary students whose studies have been interrupted while on active service. Many of these will, without financial assistance, be unable to complete their training.

2. Discharged officers and men who wish to enter the veterinary profession, but whose means are insufficient to enable them to undertake the four years' course required for qualification.

*Recommendations.* 1. The award of scholarships to deserving students on the recommendation of the Principals of the affiliated veterinary teaching schools, after full investigation into the circumstances of each case.

There are about 140 students on active service. Possibly half of these will require financial assistance. Fifty scholarships of £50 per annum each, for one, two, three or four years as may be required, should be available. £7500 would probably cover the cost, allowing an average of three years as the period required for qualifying.

2. In the case of the second category of candidates, wherever possible, having regard to the applicants' general education, the conditions concerning preliminary education should be somewhat modified.

The General Medical Council recognises a number of teaching institutions other than recognised schools of medicine, as institutions at which medical study may be commenced. It is recommended that the Council of the R.C.V.S. should in special cases, where for any reason the candidate could not attend for the first professional course at one of the affiliated schools, recognise his attendance at an approved teaching institution for courses in Chemistry and Elementary Physics, and Biology (Botany and Zoology) on the understanding

(a) That the candidate submit himself for the first professional examination in the subjects of Chemistry and Elementary Physics and Biology at one of the centres of such examination arranged by the R.C.V.S.

(b) That the whole subject of Anatomy to be taken at the second year's professional examination.

In view of the importance of maintaining the standard of education for veterinary surgeons, no reduction in the length of the professional course can be recommended except as indicated above.

Students whose circumstances would otherwise preclude their giving up four years in order to qualify for the profession should in approved cases be eligible for scholarships of say £50 a year for four years, re-

newable if necessary for a longer period on the recommendation of the Principal of the school attended. The number and value of the scholarships should be determined by the Ministry of Labour in conjunction with the Ministry of Pensions, bearing in mind the fact that the tuition and examination fees will amount to about £30 per annum, apart from the cost of books, instruments and maintenance expenses.

*Re-settlement of Officers in civil life.* Mr. Garnett reported that he had attended a meeting of the Re-settlement Committee under the Ministry of Labour as representative of the R.C.V.S. when Sub-Committees were appointed, and other preliminary steps taken.

It was resolved that the report be received and adopted.

*Educational Certificates.* Nos. 1712-1721 were submitted, and with the exception of Nos. 1716 and 1717 were approved.

*Examination of student-prisoner in Germany.* It was resolved: That the arrangements for the examination of a student-prisoner in Germany be left in the hands of the President and Chairman of the Examination Committee.

*Correspondence.* An application was received from Mr. T. R. Thomas, a third-year student, for a special examination in Stable Management at the December examination.

It was resolved: That arrangements be made for Mr. T. R. Thomas to be examined in Stable Management and Manipulation of Domesticated Animals and Principals of Shoeing Healthy Animals, by the Examiners in Hygiene and Dietetics at the Class C examination to be held in December.

An application was received on behalf of Mr. E. R. Ambrose, rejected in Class A in the subject of Chemistry only, and now in His Majesty's Forces, for a special examination in Chemistry at the December examinations.

It was resolved: That arrangements be made for Mr. E. R. Ambrose to be examined in the subject of Chemistry alone at the December examinations, and that if successful he be considered as having passed Class A examination.

Correspondence with the High Commissioner for the Union of South Africa was submitted asking what exemption, if any, would be granted to Mr. J. Martinaglia, South African student, who has passed his second year's course at the Ontario Veterinary College, if he transferred to the R.V.C., London. The Secretary was instructed to reply that no exemption could be allowed.

An application by Mr. J. Allport, medical student, for exemption from part of the four years' course.

It was resolved: That the matter be deferred for further enquiry.

An application by Mr. R. Bretherton, holder of the National Diploma in Agriculture, for exemption from the preliminary educational examination. The matter was deferred pending enquiries to be made by the Secretary as to the nature of the preliminary educational examination, if any, required by the National Agricultural Examining Board.

An application from Mr. W. Pearson, a soldier, for exemption from the preliminary educational examination in view of other certificates possessed. The matter was deferred for further enquiry.

*Recognition of Irish.* Correspondence was received with regard to the decision of the Council to discontinue its recognition of Irish as an approved modern language for the purpose of the preliminary educational examination.

It was resolved: That the decision of the Council be adhered to, but that the Secretary be instructed to make enquiries as to the practice of other professional bodies in this matter.

**Resignation of Examiner.** A letter was received from Mr. H. C. Reeks tendering his resignation as examiner in Pathology and Bacteriology in Class C.

It was resolved: That the resignation of Mr. H. C. Reeks be accepted with regret, and that the Secretary be instructed to convey to him the thanks of the Council for his past services.

Other correspondence was submitted and the Secretary was instructed as to the replies to be sent.

Mr. SHARE-JONES: Is the approval of the report a matter of great urgency to-day? It strikes me as being a very important and very comprehensive report, and it might be wise to circulate it to each member for discussion at the next meeting, unless there is something very urgent about it.

The PRESIDENT: Which part of the report are you referring to, the part dealing with assistance to veterinary students after the war?

Mr. SHARE-JONES: Chiefly.

The PRESIDENT: The circumstances in connection with that are these. A Sub-committee went into this matter, and they reported to the Examination Committee yesterday, and the matter was then thoroughly gone into. I myself think it is very urgent that this should be presented to the Ministry of Labour and the Ministry of Pensions at the earliest possible moment.

Mr. SHARE-JONES: I am not taking exception to the report, but I only mention the fact that, in the case of an elaborate document such as that which has just been read, it is quite a usual request to make that it should be circulated to each man who is called upon to vote on it. However, I do not raise any objection to it.

The PRESIDENT: In my opinion it is very urgent, and I think it should be presented as quickly as possible.

Mr. SHARE-JONES: So far as applies to the curriculum, it is simply and solely a war measure?

The PRESIDENT: That is so. It only applies to those persons who have served in the war, that is to say, since the 3rd August, 1914.

Dr. BRADLEY: I propose the adoption of the report.

Maj.-Gen. THOMSON seconded the motion, which was carried unanimously.

#### PARLIAMENTARY AND GENERAL PURPOSES COMMITTEE.

Dr. BRADLEY read the report of a meeting held on the 3rd October:—

*Chairman.* It was resolved: That Dr. O. Charnock Bradley be appointed to the Chair.

#### *Sub-Committee on Veterinary Surgeons' Bill for South Africa.*

The following report of the Sub-Committee appointed to draft a report and suggested reply to a letter received from Col. J. Irvine Smith relating to the proposed Veterinary Surgeons' Bill for South Africa was received and approved:—

The object of the Bill is to provide a Council of Veterinary Surgeons in the Union of South Africa for the following purposes:—

- (a) The admission and registration of persons as Veterinary Surgeons.
- (b) Disciplinary powers with regard to them.
- (c) Protection of the profession and public from unqualified persons.

There is no provision enabling the Council to make regulations as to the studies or examination of candidates, but the Governor-General is to prescribe (with certain limitations) what diplomas or certificates are to entitle to admission (Section 22). There is nothing in the Bill to specify length of course of study, or number, nature, mode or quality of examinations.

Diplomas granted in the United Kingdom or a British possession are to entitle to admission unless the Council satisfy the Governor-General that such diploma granting body has refused to grant reciprocal privileges to

persons who have qualified after examination in the Union (Section 22 (2)). This sub-section seems to be incomplete, but there is no doubt as to its intention. It will not affect the present holders of such diplomas if they apply for registration within one month after the passing of the Act (Section 22 (3)).

It will, however, shut out future applicants having the diploma of the Royal College of Veterinary Surgeons unless the College gives a reciprocal privilege, and this the College could not be advised to agree to in the present uncertainty of the qualifications necessary for registration in the Union.

The framer of Clause 22 (2) appears to have been under the impression that it was competent for the Royal College of Veterinary Surgeons to enter into some sort of bargain to admit holders of the Union of South Africa diploma if the Union admitted members of the College; but the Royal College of Veterinary Surgeons has no such power. Section 12 (1 and 3) of the Veterinary Surgeons Act, 1881, is definite on this point—that a recognised veterinary diploma is a veterinary diploma recognised for the time being by the Council of the Royal College as furnishing guarantee of the possession of the requisite knowledge and skill for the efficient practice of veterinary surgery. The Royal College of Veterinary Surgeons' judgment of what constitutes such a guarantee is evidenced by what is required from students before issuing to them its own diploma. It is suggested that the difficulty might be met by the insertion of a similar clause to Section 13 of the Veterinary Surgeons Act, 1881, in place of Sub-section 2 of Section 22 of the Bill.

Members of the Royal College of Veterinary Surgeons resident in the Union will be disqualified unless they apply for registration within one month after the Bill becomes law. The period is quite inadequate, especially during the war, since some of those members are on active service in various parts of the world and might fail to learn anything about the Bill for a considerable time after it is passed. The interval ought to be at least a year.

At the present time there are in this country a number of students who have come from the Union of South Africa in order to obtain the diploma of the Royal College of Veterinary Surgeons. Some of these have only passed the A examination and, therefore, cannot qualify till 1921, and probably other students are now on their way to begin the curriculum in October. Some of those already here were actually sent by the Union Government and have Scholarships to enable them to qualify.

Unless the Royal College of Veterinary Surgeons gives so-called reciprocal privileges to every person registered under the Bill in the Union, these students, when they qualify, will be unable to register in the Union, and it is quite certain that at least for years to come we shall not be able to grant reciprocal privileges (owing to absence of evidence regarding the standard of the teaching and of the examinations in the Union).

This is a very serious matter for the students in question, and the Council ought to take steps to ensure that their future is safeguarded in the Bill. This might be done by introducing words to the effect that:—

"Notwithstanding anything in the Bill, registration may be granted to any member of the Royal College of Veterinary Surgeons who was born in the Union of South Africa, and who at the date of the passing of the Bill was a *bona fide* student at a recognised Veterinary College in the United Kingdom."

It is suggested that some provision should be inserted for the imposition of a registration fee in order to provide funds for the carrying out of the provisions of the Bill.

The Sub-Committee suggest that a letter should be written by the Secretary to the High Commissioner for

the Union of South Africa setting out the views of the Royal College of Veterinary Surgeons, and that a copy of this should be enclosed in a covering letter to Col. Irvine Smith.

*Mettam appeal for Civil List Pension.* Correspondence on this matter was submitted, but its consideration was deferred pending further enquiries.

*Supplies of Linseed Oil.* The President reported that he had had an interview with the Chairman of the United Kingdom Linseed Oil Association, acting under the Ministry of Food with regard to the supplies of Linseed Oil for use in Veterinary Practice, and for agricultural purposes. He had made suggestions with regard to the disposition of the limited supplies available, and a further report on the matter would be submitted at the next meeting of Council.

It was resolved: That the action of the President be approved.

*Clean Milk Supply.* A letter from the Director of Milk Supplies (Ministry of Food) with regard to veterinary fees for carrying out the tuberculin test was submitted, and it was resolved: That the Chairman and Sir John M'Fadyean be asked to draft a reply to submit to the next meeting of Council.

*Veterinary Fees.* A letter was received from the Secretary of the Midland Counties Veterinary Medical Association conveying a report of a discussion at a meeting of the Association held on August 21st, and expressing the opinion of the Association that it is desirable in present circumstances that the fees of veterinary surgeons should be substantially raised. The Secretary was instructed to reply that this Committee concurs in the opinion expressed by the Midland Counties Veterinary Medical Association.

A letter was received from Major H. G. Simpson, and the Secretary was instructed to reply that the matter is not one on which the Committee can make any recommendation.

Mr. SHARE-JONES: I should like to move that the report be circulated to the members of the Council, and that the vote on it be taken at the next meeting. It is a report of engrossing interest. Personally I was somewhat disappointed to find that the Committee have not, so far as I gathered from the reading of the report, expressed any opinion at all to the Council as to the principle of conceding this application, supposing the conditions in South Africa were favourable. I think that is a matter on which they might have offered some opinion to the Council. I think I am justified in asking that, in the case of an important document of this kind, it should be circulated to the members before they are called upon to vote.

Mr. THATCHER (Solicitor): May I suggest that there is some amount of difficulty in adopting that course. I do not know that this Act is not in operation now in South Africa, and no time should be lost in putting forward this protest. It is some time since the Bill was put in the hands of the Committee, and I think the sooner some protest is made to the High Commissioner the better, or we may find that, while we have been deliberating on the Bill, an Act has actually been passed. The matter seems to me to be urgent.

The PRESIDENT: This is another matter that was referred to a small Committee. The Bill is a very voluminous one; it covers many pages of printed matter, and it has been very carefully gone into by the Solicitor and the Sub-Committee which reported to the main Committee yesterday; and I think it would be detrimental to the interests of the profession if the report were not passed to-day.

Mr. SHARE-JONES: I do not wish to be disrespectful to the Solicitor or the Committee, but it does appear to me as though the Committee have dealt with this problem with the ultimate object of securing such evidence as they could possibly secure to refuse the

application of South Africa. In the present state of International politics there is another side to the question, and it might prove ultimately very detrimental to the profession as a whole if the subject were not approached in a more sympathetic manner. However, I am not in a position to enter into detailed criticism of a report which I have simply heard read.

The PRESIDENT: I can assure Mr. Share-Jones that such a proposition as he is thinking about, that is, reciprocal treatment, will come up in due course whenever there is a College founded in South Africa which asks us to accept their members, but until that circumstance does arise—and it is not probable, certainly within the next two or three years—I think this is the only action we can take.

Mr. SHARE-JONES: With that assurance I am quite satisfied.

Sir JOHN M'FADYEAN: May I say, as a member of the Sub-Committee, that I think Mr. Share-Jones is under a misapprehension as to the nature of the proposal, if it can be so-called, that was submitted to us? As I understand it, no actual proposal has been submitted to us. We were asked to consider the terms of this Bill, which introduces legislation that will affect members of the profession in South Africa only, and what we felt we had to do was to see that the Bill contained no provisions which, so to speak, contravened the interests of the members of this College. We have dealt only with the points in the Bill which seemed, so to speak, to touch our interests. It is true that in the Bill the expression "grant of reciprocal privileges" is introduced more than once, but, as we have pointed out, the expression has been used in consequence of a misapprehension on the part of those who drafted the Bill with regard to what action is possible by us. But there is no question of being sympathetic or unsympathetic; we dealt with the situation as it exists at the moment, and as it is likely to continue to exist for a number of years. That is to say, we cannot make a bargain with the Government of South Africa that we will recognise, as the equivalent of our own diploma, a diploma that is not yet in existence and regarding the obtaining of which no conditions have been formulated, even in outline. I repeat that there is no question of want of sympathy with regard to the objects of those who promoted the Bill.

On the motion of Dr. Bradley, seconded by Mr. Clarkson, the report was then adopted.

#### PUBLICATION, LIBRARY, AND MUSEUM COMMITTEE.

Mr. SHARE-JONES read the following report of a meeting held on October 4th:—

It was resolved: That Dr. Share-Jones be appointed Chairman of the Committee for the ensuing year.

*Presentations to Library.* The Secretary reported that since the previous quarterly meeting the following presentations had been made to the Library.

*Annual Reports:* Veterinary Division, Union of South Africa, 1916-17; S. Rhodesia, Chief Veterinary Surgeon, 1917; Board of Agriculture for Scotland, Agricultural Statistics, 1916, Vol. V, Part I, Acreage and Live Stock Returns Agriculture Statistic, 1915, Vol. IV, Part III, Prices and Supplies of Grain, Live Stock, etc.

A Compendious System of Veterinary Instruction, by B. Bull, 1835; presented by Mr. W. H. Brown.

*Reprints:* Veterinary Diseases and the Vicious Circle, J. B. Hurry (v.n.); Eupatorium Urticæfolium as a Poisonous Plant, by D. D. Marsh and A. B. Clawson, reprinted from *Journal of Agricultural Research*, Washington; Destruction of Tetanus Antitoxin by Chemical Agents, reprinted from *Journal of Agricultural Research*.

*Bulletins:* Some Camel Feeding Experiments, by H. E. Cross; Dehorning and Castrating Cattle, by F. W. Farley; Hemorrhagic Septicæmia, by H. J. Washburn;

Breeds of Light Horses, by H. H. Reese; The Four Essential Factors in the Production of Milk of Low Bacterial Content, by S. H. Ayres, L. B. Cook, P. W. Clemmer; Some Notes on Medical Education in England, by Sir G. Newman.

*Calendars:* The Ontario Veterinary College, 1918-19; McKillip Veterinary College, 1918-19; Indiana Veterinary College, 1918-19.

*Periodicals:* The Journal of the Board of Agriculture and Fisheries; The Journal of the D.A.T.I., Ireland; Journal of Comparative Pathology and Therapeutics; Revue de Pathologie Comparée; Journal of Physiology (per Maj.-Gen. Sir F. Smith); Rhodesia Agricultural Journal; New Zealand Journal of Agriculture; Journal of Department of Agriculture, Melbourne, Victoria; The Bloodstock Breeders' Review; The Veterinary Review; The Veterinary Journal; The Veterinary Record; The Veterinary News; The British Medical Journal (per Dr. Bradley); The Educational Times.

It was resolved: That a vote of thanks be accorded to the respective donors.

*Subscriptions to Periodicals.* The Secretary was instructed to renew the annual subscriptions for the usual periodicals purchased.

*Register, 1919.* It was resolved: That the Register for 1919 be printed in the same form as for the present year.

*Publication of Bye-Laws.* It was resolved: That 100 copies of the Bye-Laws be printed, to be sold at a price to cover the cost.

On the motion of Mr. Share-Jones, seconded by Dr. Bradley, the Report was received and adopted.

#### WAR EMERGENCY COMMITTEE.

The SECRETARY read the following report of a meeting held on October 3rd:—

It was resolved: That the President be appointed to the Chair.

*Veterinary Tribunal.* The following Order of the Local Government Board was read:—

In pursuance of the provisions of Regulation 54 of The Military Service Regulations, 1918, the Local Government Board and the Secretary for Scotland hereby appoint:—

F. W. Garnett, Esq., C.B.E., M.R.C.V.S.  
G. A. Banham, Esq., F.R.C.V.S.  
Hugh Begg, Esq., F.R.C.V.S.  
O. Charnock Bradley, Esq., M.D., D.Sc., CH.B., M.R.C.V.S.  
J. Clarkson, Esq., M.R.C.V.S.  
H. J. Dawes, Esq., F.R.C.V.S.  
Sir J. M'Fadyean, Esq., LL.D., M.B., C.M., B.Sc., M.R.C.V.S.  
W. J. Mulvey, Esq., F.R.C.V.S.  
S. H. Slocock, Esq., F.R.C.V.S.  
J. Willett, Esq., M.R.C.V.S.  
P. Wilson, Esq., M.R.C.V.S.  
W. Woods, Esq., F.R.C.V.S.

to be a Special Tribunal (hereinafter called the Veterinary Tribunal) for the purpose of dealing, on and after the twenty-eighth day of August, 1918, with any application, or request for leave to make application, for the grant, renewal, variation or withdrawal of a certificate of exemption to, or held by, any man (not being a duly qualified medical practitioner), who is a qualified veterinary surgeon registered under the Veterinary Surgeons Act, 1881. F. W. Garnett, Esq., C.B.E., M.R.C.V.S., is hereby appointed to be Chairman of the Veterinary Tribunal.

And the Local Government Board and the Secretary for Scotland direct that the powers, functions and procedure of the Veterinary Tribunal in relation to the matters aforesaid shall be the same as those of an Appeal Tribunal when dealing with applications, or request for leave to make application, made direct to

them under the Military Service Regulations, 1918, as amended by subsequent Regulations.

Dated this twenty-first day of August, 1918,

W. HAYES FISHER,  
President of the Local Govt. Board.  
ROBERT MUNRO,  
His Majesty's Secretary for Scotland.

*Exemption and Release of Veterinary Students.* The Secretary reported that he had had an interview at the Ministry of National Service with regard to the question of the release and exemption of veterinary students, and had supplied the Ministry with full particulars respecting the names, addresses, ages and medical grades of all registered veterinary students, making the request that the students at present registered in the Colleges should be made exempt from military service irrespective of age and medical category, and that bona fide veterinary students now service with the colours should be demobilised to complete their studies.

It was resolved: That the action of the Secretary be approved.

On the motion of the President the report was unanimously adopted.

The PRESIDENT: There is one thing I omitted at the Special Meeting we held about the formation of the Veterinary Tribunal, and that was to ask the permission of the Council that Mr. Bullock might be allowed to serve as Clerk to that Tribunal. I take it that it is your wish that that be so. (Agreed to.)

#### HONOURS AND PRIZES COMMITTEE.

Mr. BANHAM read the following report of a meeting held on October 4th:—

It was resolved: That Mr. Banham be appointed to the Chair.

*FitzWygram Prize.* The Secretary read the report of the Auditors on the number of marks gained by the students eligible for the FitzWygram prizes, from which it appeared that Mr. T. Kelleher of the Royal Veterinary College, Ireland, reached the first place with 773 marks, and Mr. J. McCunn of the Royal Veterinary College, London, reach the second place with 731 marks.

It was resolved: That the FitzWygram Prizes, 1918, be awarded:—First Prize, T. Kelleher; Second Prize, J. McCunn.

*Steel Memorial Medal.* It was resolved to recommend: That the Steel Memorial Medal be awarded to Dr. Griffith J. Evans, M.B., C.M., M.R.C.V.S.

*Honorary Associates.* Recommendations for election as Honorary Associates were submitted and considered. It was resolved: That the matter be deferred for the time being.

Sir JOHN M'FADYEAN: There is one matter arising in connection with the report that has just been read that I should like to raise, and that is the question whether we have the power, and if we have the power whether we should exercise it, of suspending the award of these prizes until the conclusion of the war, until the size of the classes becomes normal. I am sorry to have to admit that, if there is any force in the remarks which I am making, I ought to have made them sooner, but I think everyone who considers the position would admit that things have really become absurd, that is to say the number of students eligible for these prizes is so small as to deprive their award of any honour. I would suggest that we should find out whether we have the power and whether we should exercise it. If we have no power of course we cannot exercise it. I would suggest that the matter be referred to the Examination Committee.

The PRESIDENT: I think that is the best thing to do.

Sir JOHN M'FADYEAN: What I mean is that when there are only a quarter of the candidates that used to be eligible, it is not much of an honour to gain the prize.

The PRESIDENT: It is set out in the bequest that two prizes shall be awarded in the month of August of each year, but I think it might be quite possible, with the consent of the Charity Commissioners, to withhold the giving of them during the period of the war, or something like that. I quite agree that the size of the classes is simply absurd.

Mr. THATCHER (Solicitor): I would not like to express a view on the matter at present until I have more carefully considered it.

Mr. GAIGER: Should we not, if we defer the award until after the war, also set a limit for a minimum of marks, taking the average obtained for the last twenty years, otherwise you may be doing injustice to a brilliant student?

The PRESIDENT: We cannot do that because the prizes are given to the students obtaining the highest number of marks awarded for certain examinations. If the matter is referred to the Examination Committee Mr. Thatcher has promised to go into the legal aspects of the matter and see what we can do with regard to the views expressed. I think we might leave it in that way; it will be much the best way of dealing with it.

Major-General BLENKINSOP: It is a great pleasure to me to hear that the Council proposes to award the Steel Memorial medal to a gentleman who has done for this profession probably one of the biggest things that has ever been done for it. Dr. Griffith Evans was in Army veterinary service in India, and he was the first man to find the pathogenic trypanosomes in animals, which are now at the present time giving an enormous amount of trouble in India. He led all the scientific world on this one point, and I think this is quite the proper time when we should say something as a Council of the great work this officer has done for the profession as a whole.

On the motion of Mr. Banham, seconded by Mr. Clarkson, the report of the Committee was unanimously adopted, it was also agreed that the question raised by Sir John M'Fadyean should be referred to the Examination Committee.

SECRETARIES OF BOARD OF EXAMINERS IN SCOTLAND, LIVERPOOL AND IRELAND.

On the motion of Mr. Mulvey, seconded by Mr. Banham, it was unanimously resolved that Mr. Blackhurst, Mr. Archibald Burt, and Mr. Finlay Kerr, should be re-appointed to the positions they at present hold.

#### NOTICES OF MOTION.

The PRESIDENT: I give notice of the following alteration to Bye-law 61:—

After the first clause to add the words "Together with a certificate of birth."

Also an addition to the Bye-law of the following words:—"In any special circumstances arising in connection with the war, exemptions or other concessions may be granted by the Council on the recommendation of the Examination Committee to any person who has served in one of His Majesty's Forces since the 3rd day of August, 1914."

Prof. S. H. GAIGER: I beg to give notice of the following alteration of Bye-law 63A, that it shall read as follows:—"(a) A course of not less than 80 lectures on the Pathology, Bacteriology and Protozoology of the domesticated animals.

(b) Practical Pathology. A practical course extending to not less than 40 hours' instruction on the Pathology, Bacteriology and Protozoology of the domesticated animals."

Mr. MULVEY: I beg to give notice that at the next meeting of Council I shall move the following alteration to Bye-law 62A:—

"(1) A student who has obtained a degree in Arts, Science, or Medicine, or a degree or diploma in Agri-

culture granted by a University situate within the United Kingdom, or by any other body whose degree or diploma in Agriculture is approved for the time being by the Council on the recommendation of the Examination Committee, or the diploma of Licentiate of one of the Royal Colleges of Surgeons, or of one of the Royal Colleges of Physicians, and who in procuring any such degree or diploma passed an examination in Chemistry and also in Biology, Zoology or Botany, shall be exempted from his A or first professional examination, and the bye-laws and regulations in respect thereof, and shall be entitled in all respects to the rights and privileges which the passing of such examination ordinarily confers, provided always that such student so exempted shall be examined in the whole subject of Anatomy in the Class B examination.

(2) A student possessing a degree or diploma of a like import or denomination to one of those enumerated in paragraph 1 hereof, but granted by a University or other examining or licensing authority other than those mentioned in paragraph 1 shall, if the Council declare its sufficiency for exemption, thereupon become entitled in all respects to such exemptions, rights and privileges as are defined in paragraph 1 of this bye-law."

#### V.V.B. FUND—REGISTERED OFFICE.

The SECRETARY: I am requested, on behalf of the Council of the Victoria Veterinary Benevolent Fund, to ask this Council for permission to display a notice outside this building to the effect that the registered offices of the Victoria Veterinary Benevolent Fund, Incorporated are at this address. It is necessary to display such a notice as soon as the Victoria Veterinary Benevolent Fund becomes incorporated under the Companies Consolidation Acts.

Mr. MULVEY: That means a brass plate on the door outside?

Mr. THATCHER (Solicitor): It may be put up anywhere there.

The PRESIDENT: Subject to the approval of the Treasurer, I think we might grant that request. There will be nothing objectionable about it in any way.

Permission was then granted in the terms desired.

This concluded the proceedings of the Quarterly Meeting of Council.

#### SPECIAL MEETING.

Immediately following the quarterly meeting, a Special Meeting of Council was held, presided over by the President, Mr. F. W. GARNETT, C.B.E., J.P., and the same members were present as at the quarterly meeting.

The Minutes of the last Special Meeting, which had been printed and circulated, were taken as read and confirmed.

#### ALTERATION TO BYE-LAW 80.

Sir STEWART STOCKMAN moved the following alteration to Bye-law 80, of which he had given due notice.

"Each candidate for the office of Examiner shall, at least fourteen days before the election, intimate in writing to the Secretary his willingness to be appointed, and submit with his application a statement of his qualifications . . ."

The remainder of the Bye-law to stand as at present.

He said: Bye-law 80 as it stands at present is somewhat ungrammatical. It contains a rather anomalous provision, namely, that a candidate for examinership for this College can apply through a member of the College instead of to the Secretary. The amendment which I now propose aims at altering that, so that any candidate for an examinership will apply directly to the Secretary, saying that he is willing to be appointed, and submitting with his application a statement of his qualifications. I beg to move the alteration.

Sir JOHN M'FADYEAN seconded the motion, which was carried unanimously.

*Alteration to Bye-law 62a.* Mr. MULVEY: I rise to ask permission to withdraw the notice of motion which I have given.

The PRESIDENT: I take it that the Council will grant that request. (Agreed to).

The notice given by Mr. Mulvey for the alteration of Bye-law 62a was as follows:—

(1) A student who has obtained a degree in Arts, Science or Medicine, or a degree or diploma in Agriculture granted by a University situate within the United Kingdom, or by the Joint Examining Board of the Royal Agricultural Society of England and the Highland and Agricultural Society of Scotland, or by any other body whose degree or diploma in Agriculture is approved for the time being by the Council on the recommendation of the Examination Committee, or the diploma of Licentiate of one of the Royal Colleges of Surgeons, or one of the Royal Colleges of Physicians, and who in procuring any such degree or diploma passed an examination in Chemistry and also in Biology, Zoology or Botany, shall be exempted from his A or first professional examination, and the bye-laws and regulations in respect thereof, and shall be entitled in all respects to the rights and privileges which the passing of such examination ordinarily confers, provided always that such student so exempted shall be examined in the whole subject of Anatomy in the Class B examination.

(2) A student possessing a degree or diploma of a like import or denomination to one of those enumerated in paragraph 1 hereof, but granted by a University or other examining or licensing authority other than those mentioned in paragraph 1 shall, if the Council declare its sufficiency for exemption, thereupon become entitled in all respects to such exemptions, rights and privileges as are defined in paragraph 1 of this bye-law. In any other special circumstances arising in connection with the war, exemption under this bye-law may be granted by the Council on the recommendation of the Examination Committee.

It was agreed that the Confirmatory Meeting of the Council should be held on Friday, the 18th inst.

*The Steel Memorial Medal.* The PRESIDENT: With regard to the award of the Steel Memorial Medal to Dr. Griffith Evans, it is almost certain he will not be able to attend at this Council. He is a very old gentleman and is confined to the house, and in the event of his saying that he cannot attend, I take it that it is your wish that the Medal should be sent to him with a suitable letter.

Mr. BANHAM: I propose that.

Mr. CARTER seconded the motion, which was carried unanimously.

A hearty vote of thanks having been accorded to the President for his conduct in the Chair, the meeting terminated.

### THE VETERINARY TRIBUNAL

The first meeting of the Veterinary Tribunal was held at 10 Red Lion Square, London, W.C., on Wednesday, October 2nd, 1918, when all the members were present, the chair being occupied by Mr. Frank W. Garnett, C.B.E., M.R.C.V.S.

The SECRETARY read the Order constituting the Tribunal, a copy of which has already been published.

On the proposition of Mr. Garnett, seconded by Mr. Dawes, it was unanimously resolved that Mr. W. J. Mulvey, F.R.C.V.S., be appointed Deputy Chairman of the Tribunal.

The CHAIRMAN proposed, and it was unanimously carried, that Mr. F. Bullock, F.C.I.S., be appointed Secretary to the Tribunal.

The general question as to the sources of supply of duly qualified veterinary surgeons, either for commissions in the A.V.C., or for substitutes to release younger men now in civil practices in order that they may be rendered available for commissions, was considered, and a recommendation was passed urging the importance of the release and exemption of veterinary students in order that they may continue their studies and complete their qualification.

The Secretary was instructed to report to the National Service Representative all cases coming under his notice where exemption has been granted by Local Tribunals to unregistered persons acting as veterinary practitioners.

The following cases were then dealt with:—

Mr. A. M. Wylie, M.R.C.V.S., of The Dell, Grays, Essex, Temporary exemption for three months was granted.

Mr. W. Crawford, M.R.C.V.S., of 155 Woodhouse Lane, Leeds. The National Service Representative's appeal was dismissed, and a temporary exemption for six months was granted.

Mr. A. J. Horner, M.R.C.V.S., Evelyn House, Witham, Essex. Temporary exemption for six months was granted.

Mr. G. H. Williams, M.R.C.V.S., of 2 Langley Road, Chippenham. Temporary exemption for six months was granted.

In each case exemption was also granted from training with the Volunteers.

### NEXT MEETING.

The next meeting of the Veterinary Tribunal will be held at 10 Red Lion Square, on Friday, 18th October, at 11 a.m.

The Tribunal is open to the public: as all other such tribunals.

### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

## "WHO IS TO BLAME?"

To the Editor, "The Veterinary Record."

Dear Sir,—There is one aspect of the insurance of live stock in which we as veterinary surgeons are sometimes placed in an awkward position—I refer to the granting of post-mortem certificates on non-inspected animals.

Take, for instance, a horse that is insured without veterinary examination. The animal is taken ill; the owner—a good client, sends for his veterinary surgeon, treatment is adopted, but it is a serious case and the animal dies. Or take another case in which the veterinary surgeon is only called in to make a post-mortem and report. In the policy the age is given as ten years, and the insured value is £80.

The veterinary surgeon finds the horse is not less than eighteen years of age, and in his opinion the insured value £50. How is he to act? Is the vety. surgeon to adhere to his opinion in giving a certificate and thus play into the hands of the insurance company, so that they can squabble over the claim, and for himself the possible loss of a good client; or is he to squash his opinion and follow the lines of the policy?

Cases of this kind are of frequent occurrence. Personally I try to follow the lines of the policy as far as possible, on the principle that if an insurance company takes on such a risk, they are quite liable to pay in the event of a claim.

However, this state of affairs should not exist, no animal should be insured unless a veterinary report has been furnished. Of course, this is a matter for the insurance companies only; if they let themselves in for bogus claims the only one to benefit is the insurant.

"PUZZLED."

## QUACK VETERINARY REMEDIES.

Sir,—With reference to the articles appearing in the V.R. respecting patent medicines; as they are not stamped I think the above name more applicable. Really the amount of quackery is measured by the label on the bottle. How do some members of our profession stand? I have seen finely coloured labels with a horse, cow and sheep on them, four inches deep, on a six ounce bottle, labelled colic or gripe drink; and it cured all animals above mentioned not only of colic, but about a score of other ailments, including calving cows and lambing ewes. Then, of course, there was another bottle containing white oils, which was a specific for all external affections, etc., lameness, sore throats, coughs, strangles, swollen bags in cows and sheep. With a bottle or two of these, the farmer could dispense almost with his veterinary surgeon, and leave him to seek help in his old age from the Victoria Benevolent Fund.

I have always had a great aversion to quackery in any form; and I think if more discretion were used in the use of labels it would raise the status of our profession very much. Any reader who sends to a veterinary label printer for samples will be able to prove what I have said on that point.

If we adjust matters inside the profession it will be an easier matter to alter matters outside.

GEO. E. GIBSON, M.R.C.V.S.

Newport Pagnell.

MIDLAND COUNTIES V.M.A.—CORRECTION.

To the Editor, "The Veterinary Record."

Dear Sir,—In the report of the meeting of the Midland Counties V.M.A. I am reported to have said that the ther-

ometers I used registered 100° F. It was 110° F. that they registered. The mercury in the first thermometer rose to the very top and broke the thermometer. I therefore sent for another, but as it also only registered to 110 I was unable to find the true temperature of the patient, which was, of course, over 110.

With regard to grease, said that I prepared the skin for treatment by clipping the hair as short as possible, and then washing with a hot solution of soft soap and cresol. I then dried the skin, and washed it with petrol, thus removing all secretions.

Tenbury.

JAMES M. WHYTE, M.R.C.V.S.

### ARMY VETERINARY SERVICE

War Office, Oct. 7.

The following names are to be added to those brought to notice for distinguished services by Lt.-Gen. Sir J. L. Van Deventer, K.C.B., in his dispatch of Jan. 21, 1918:—

\* \* \*

Major W. Kennedy, East African Vety. Corps.

The following is now correctly described:—

*Gazette* dated May 20, 1918—Capt. (temp. Maj.) J. L. C. Jones, A.V.C.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Oct. 4.

#### REGULAR FORCES. ARMY VETERINARY CORPS.

Capt. D. R. Williamson, Spec. Res., relinquishes the actg. rank of Maj. on ceasing to hold the appt. of Dep. Asst. Dir. of Vety. Servs. (Aug. 8).

Temp. Capt. E. Salusbury relinquishes his commn. on account of ill-health contracted on active service, and is granted the hon. rank of Capt. (Oct. 5).

Oct. 8.

Capt. R. F. Bett to be actg. Maj. whilst holding the appt. of Dep. Asst. Dir. of Vety. Servs. (Mar. 8) (substituted for notification in the *Gazette* of June 24).

Temp. Capt. (Bt. Maj.) S. L. Symonds to be actg. Maj. (June 15).

Capt. to be actg. Maj. :—S. W. Marriott (June 15); W. H. Simpson (July 25); C. Davenport (July 29); R. F. Stirling, F.R.C.V.S., Spec. Res. (Aug. 22).

Temp. Capt. G. S. Arkcoll relinquishes his commn. on acct. of ill-health and is granted the hon. rank of Capt. (Oct. 9).

Oct. 9.

To be temp. Lt. :—W. B. Davidson (Aug. 29).

### OBITUARY.

JAMES HENRY TURNOR KENYON, Hon. Capt. A.V.C.  
Graduated, N. Edin : April, 1874.

Died, Savoy Hospital, Blackpool, Sept., 1918, aged 67.

WILLIAM BENNETT, "Existing Practitioner," Odessa Street, Dowlais, Glam.

Mr. Bennett died on October 1st, aged 60.

KITCHEN.—On the 2nd Oct., at Bournemouth, after years of suffering borne with Christian fortitude, Elizabeth Frances (Lizzie), the dearly-loved wife of James Edward Kitchen, M.R.C.V.S., of Glengall Lodge, Woodford Green, Essex. A devoted wife and mother.

### Balliol College A.-A. Sale.

The entire herd of pedigree Aberdeen-Angus cattle owned by the late Dr. Clement Stephenson was dispersed at Balliol College Farm, Benton, Newcastle, on Thursday, Oct. 3, by Messrs. Macdonald, Fraser & Co. (Ltd.). During the forty years he was a breeder of Aberdeen-Angus cattle, the late Dr. Stephenson paid the closest attention to soundness of constitution, milking qualities and breed character, and the success which followed his efforts is fully reflected in the long list of honours won by representatives of the herd at the principal shows. The stock were presented on Thursday in useful breeding condition, and they formed a very attractive lot, the young cows and yearling heifers being particularly good. There was a fairly good attendance, and most of those present were on the look-out for stock, with the result that a satisfactory trade was experienced.

Mr. Lovat Fraser conducted the sale, and disposed of the 52 head in less than an hour and a half. A beginning was made with the cows. The top price of the sale was 240 guineas, by Mr. Sandeman, Moredon House, Herts, for Jilt of Benton XII (53275), a beautiful five-year-old cow which has proved an excellent breeder. She was by the home-bred sire, Bright Actor (31512), and is in calf to Prince of Jesters (32404).

Yearling heifers sold well. In this section the highest figure was 180 guineas by Mr. Watt for Proud Miss (61184), by Prince of Jesters out of Pride X. of Laggan : the 130 guineas cow also secured by Mr. Watt, Proud Primrose (61185), by Prince of Jesters, was generally regarded as the plum of the heifers, and, considering her breeding and quality, she was cheap at 170 guineas to Mr. A. W. Bailey Hawkins, from Kent.

Two bulls were exposed. Newcome Laddie (42084), bred by Lord Penrhyn, Wicken Park, and which was third at Birmingham sale this year, is a thick stylish bull with capital quarters. His price was £140 guineas to Mr. Watt.

#### SUMMARY.

	Average	Total
21 cows	£79 0 0	£1659 0 0
7 bull calves	39 0 0	273 0 0
12 heifer calves	40 10 3	486 3 0
1 two-year-old heifer	—	63 0 0
9 yearling heifers	79 18 4	719 5 0
2 bulls	123 18 0	247 16 0
52 head	£66 6 3	£3448 4 0

*The Scottish Farmer.*

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1580.

OCTOBER 19, 1918.

VOL. XXXI.

## VETERINARY SOCIETIES.

We have to-day to welcome the advent of another local Veterinary Society—The Derbyshire. A short account of their initial meeting appears on p. 127. and the attendance and the names of those present augurs well for its success. The last new comer was the South Eastern, which also made a very promising start, but, like some other societies, has been badly hit by war conditions. Geographical reasons justified the existence of the South Eastern Society—it was formerly part of the Southern Counties Society, which covered a strip of the south coast 180 miles long by about 30 miles deep south to north, having a string of towns along the coast—Folkestone, Eastbourne, Brighton, Portsmouth, Southampton, Bournemouth, all well served by direct rail from London, but offering much less convenience from east to west. The consequence was that the attendance at meetings was very seldom in proportion to membership, and never in a respectable proportion to the number of men practising in the area covered by the society. Now, the strength of a society cannot be measured strictly by its membership. The real strength is in the number of members who attend the meetings, and take part in the proceedings. For this reason the two southern societies were, and probably will be again, stronger than the old Southern was alone—stronger and more effective for the welfare of the profession.

The same arguments, barring distances, will apply in the case of the Derbyshire Society. Derby, which, presumably, will be the home of the Society, is a main railway centre with a surrounding of populous towns within fairly convenient distances. Birmingham and Sheffield are each rather over 30 miles to south and north respectively; Manchester and Lincoln about 50, Leeds and Liverpool about 60 miles. So that intercommunication should not be difficult, and attendances should be good—and attendances are the chief advantage offered by these societies. Many men belong to several local societies, and find time to attend several times in the year—and there is wisdom in the procedure, even though they may occasionally get a dull meeting. Judging from the attendances at similar meetings in U.S.A., they make less difficulty in leaving a practice for a day or two; and the distances their members travel to a meeting are often much greater than our men ordinarily undertake.

The years to come will need all the unity we can get. There will be rearrangements and innovations, and our legislators then may be even less well informed and more indifferent to the affairs of others than the present men have shown themselves to be. Combinations are forming in many directions, and, as a contributor said last week, in another connection, "If we adjust matters inside the profession it will be an easier matter to alter matters outside."

## BACTERIAL INFECTION OF WOUNDS IN FRANCE.

During the period in which I was attached to a Veterinary Hospital in France, I had many cases through my hands of so-called "fibrous tumour of the neck" occasioned indirectly by bites from horses. It always seemed very strange to me why an ordinary bite should be followed by such a serious complication, and the only explanation I can offer is that there is an infection of the wound by an organism which is indigenous to France. I say "serious complication" advisedly, in view of the time required to bring about resolution, and also of the position of the injury, which is usually on the point of the shoulder or a little above. I have consistently noticed that horse bites which occur in England are not followed by any untoward complication, the wounds rapidly cicatrising and healing. In France it was a very aggravating circumstance, to say the least of it, when, having treated a mange case successfully and being about to discharge the animal, to find one morning a diffuse thickening around the site of an insignificant bite wound.

Surgical extirpation is the only successful treatment; all other methods have proved to be merely waste of time. In the large majority of cases upon which I operated, there was a small opening at the lower edge of the swelling, leading up usually into a large cavity from which there was a constant discharge of pus. No amount of curetting, or syringing with iodine or astringents, did the least good, and in fact, with every succeeding day there was an appreciable increase in the size of the area affected, and I have known cases where it would have required even a foolscap sheet of paper to cover the lesion.

Early operation, therefore, is essential, and there are two methods, one of which is to make a deep incision through skin and fibrous tissues from the opening below to the upper boundary of the swelling, and on either side the skin is then dissected carefully away from the underlying new tissue, the latter being finally removed and the skin sutured. This, however, is very difficult, as there appears to be no line of demarcation between skin and fibrous tissue—one might suppose the condition to be one of hypertrophy of the skin, so closely are the two adherent. The invading tissue has a consistency of cartilage, and attains a thickness of from  $\frac{3}{4}$  in. to 2 in., diffusing itself well up the neck and showing no tendency to diminish when once formed. The muscular tissue beneath becomes hypervascular and bleeds at the least touch, whilst in appearance its surface is roughened and glairy, and covered

with a layer of thick pus. The pus generated from wherever the wound was in apposition to the healthy tissue. However carefully this method may be carried out, the result will not prove satisfactory, as the skin has apparently lost all its vital powers and rapidly shrinks, whilst in many cases new growths of sclerous tissue are observed to form.

The other and most successful method is the radical excision of the whole swelling, including the overlying skin, by which means one is sure of removing the last particle of foreign tissue and exposing healthy tissue to the light and air. Zinc oleate ointment may be smeared over the raw surface for the next three or four days, succeeded then by dry dressing. Six to eight weeks will elapse before a hard cicatrix has formed, and the animal is fit for issue. Even then such a false skin can never replace the true skin, and collar galls are subsequently likely to be frequent.

HAMILTON KIRK, Capt. A.V.C.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### AN EXCEPTIONAL INITIAL LESION OF STRANGLES.

A. Herrera, who reported this case in the *Revista de Veterinaria Militar* for 1916 considers it of interest from its novelty. The strangles localisation in question was a metacarpo-phalangeal arthritis. This lesion, according to Hutyrá and Marek, "often develops in an acute form in advanced periods of the disease"; but it has not been reported as an initial lesion, preceding the general symptomatic manifestations and considerably before the local lesions common in, and typical of, strangles infections.

A young horse, belonging to a remount establishment, presented a warm and painful swelling of the fetlock of a fore limb.

The limb was semi-flexed, and only bore upon the ground very slightly by the fore part of the shoe. The swelling, which at first was limited to the joint, became extended to the peri-articular tissues, completely obliterating the outlines of the bones. It was extremely hard, and spread along the tendinous sheaths of the phalangeal flexors. Coincidentally with this extension of the lesion, general symptoms appeared. The horse was dull, depressed, and without appetite. The rectal temperature was nearly 103.3° F. The mucous membranes were normal.

The first treatment was purely local, consisting of bandages soaked in a 1 in 1000 sublimate solution. This treatment was followed for two days; but the local swelling extended; and the heat and pain became more intense. The general condition remained stationary; the temperature underwent slight oscillations—102.2° F. and a little over 103.6° F.; and the horse did not eat. Cantharides ointment was now applied locally; and electuary containing gentian and nux vomica were given to stimulate the appetite.

On the eighth day of the illness it was noticed that the swelling was fluctuating at its centre. The

cut was maintained; but the sensitiveness to the touch had diminished notably. The horse had weakened considerably. The temperature was higher, the pulse was small and hurried, the conjunctiva showed a cyanotic colour, and the pituitary membrane was reddened and moist. Pressure upon the throat produced cough; and the horse then ejected muco-purulent clots. Swelling of the glands of the throat began.

The swelling of the fetlock was now opened, giving exit to an abundant pus, which at first was creamy, and later thinner and streaked with blood. The pus had necrosed the suspensory ligament; and the same destructive process was commencing in the internal and external lateral ligaments.

The general state of the horse now awakened the suspicion of strangles, which was strengthened by the fact that repeated cases were appearing in the same stud. Pus from the fetlock swelling was, therefore, injected subcutaneously into a rat, and gave positive results. Moreover, the horse rapidly developed a typical strangles infection, which ran its course without showing any further unusual symptoms. Recovery was complete; but some time afterwards an irregular cicatrix still remained in the region occupied by the initial swelling.

Herrera surmises that the virus entered the organism through some solution of continuity in the fetlock region, and this infection by an unusual portal of entry produced an unusual initial lesion.—(*Revista de Higiene y Sanidad Pecuarias*).

##### THE TRANSMISSION OF CYSTICERCOSIS.

Lanlo Hugo reported an interesting case of this nature in the *Hússzemle* for 1914. A pork butcher slaughtered a young pig; the inspector discovered the existence of cysticercosis and ordered total seizure. The pig had been bought from an inhabitant of a town in Hungary; and the butcher, in accordance with the law, claimed compensation from the seller. The seller visited the inspector with regard to the identification of the pig; and the inspector was struck with the unhealthy aspect of the man. Enquiries revealed that he had suffered for a long time from attacks of vomiting, and from diarrhoea alternating with constipation. The pig he had sold had been bred by himself. The inspector upon this formed the hypothesis that the man might himself be affected with tænia and have infected the pigs which he bred. He communicated the facts to a medical man, who put the seller under treatment, and after some weeks caused the expulsion of a *Tania solium*.—(*L'Hygiène de la Viande et du Lait*). W. R. C.

##### JOURNAL OF THE AMERICAN V.M.A.

Dr. W. H. DALRYMPLE, M.R.C.V.S., has been appointed Editor of the Journal of the American Veterinary Medical Association, with office of publication at Baton Rouge, Louisiana. Dr. Pierre A. Fish, the former editor, has entered military service, hence this change became necessary.

Communications should be addressed to Dr. W. H. Dalrymple, Editor, Journal A.V.M.A., 66 Roumain Building, Baton Rouge, La.

### THE DERBYSHIRE VETERINARY ASSOCIATION.

A meeting of Derbyshire Veterinary Surgeons was held at St. James' Hotel, Derby, on Tuesday, Oct. 8th. Mr. J. T. Abell, M.R.C.V.S., of Derby, was voted to the chair.

It was decided to form an Association and that the title should be "The Derbyshire Veterinary Association. There was a large gathering, seventeen members being present, and apologies were received from others for unavoidable absence.

Mr. Alex. Levie, F.R.C.V.S., D.V.S.M. (VICT.), F.R.S.E., Derby, was elected President, and Mr. F. T. Prince, M.R.C.V.S., Ashbourne, Hon. Secretary and Treasurer.

It was agreed that the meetings shall be held quarterly, and that the Annual Subscription be 10/6.

### IMPORTANT CHANGES IN THE ARMY VETERINARY SERVICE IN INDIA.

An important advance in the Veterinary Administration of the Army in India has been made recently by the formation of a Veterinary Assistants Branch of the Indian Subordinate Veterinary Corps.

Hitherto the Indian Subordinate Veterinary Corps consisted of a few British Warrant Officers and N.C.Os. who formed the nucleus personnel of Station Veterinary Hospitals which were utilised for the treatment of the animals of British Units only.

The treatment of animals in Indian Mounted Units was carried out by the Regimental Salutri or Veterinary Assistant, the Officers Army Veterinary Corps being applied to in peace time only when contagious disease broke out. The Administrative Officers of the Army Veterinary Service carried out annual inspections of the Units, but otherwise the Veterinary Service had no direct responsibility regarding the treatment of the animals or control of the Veterinary personnel. On active service, however, the Army Veterinary Corps assumed responsibility in the same way as in the British Army.

The formation of the Veterinary Assistants Branch of the Indian Subordinate Veterinary Corps has altered all this. The Veterinary personnel of all Indian Cavalry, Artillery and Transport Units when transferred to the Indian Subordinate Veterinary Corps will come under the control of the Army Veterinary Service.

The new order improves the pay and grading of the Military Veterinary Assistants, and will tend to greatly raise their status, while the control of all the animals in the country which has now been placed in the hands of the Army Veterinary Service has greatly enlarged the scope of the Army Veterinary Corps in India.

It has long been felt that professional supervision of all the animals of the Army in India should be given to the Veterinary Service and that Service is to be congratulated on at last having been placed in its proper position in this respect.

Full text of the Army Instructions (India) with appendices is given below.

### Army Instruction (India). No. 511 1918.

SIMLA, 21st May, 1918.

#### 511. Formation of a Veterinary Assistants' Branch of the Indian Subordinate Veterinary Corps.

With the approval of the Right Honourable the Secretary of State for India, it has been decided to form a Veterinary Assistants' Branch of the Indian Subord-

inate veterinary Corps. The Corps will consist of 919 veterinary Assistants (including a reserve of 25 per cent) and will be distributed over the various grades, and among the different units, etc., as shown in Appendix III.

Veterinary assistants now serving in the various branches of the Army in India, with the exception of those employed in the Army Remount Department, will, subject to their consent, be transferred forthwith to the above branch on the terms shown in Appendix I.

The terms and conditions of service for new enrolments in this Branch are shown in Appendix II.

The extra expenditure involved is estimated at Rs. 68,109 initial and, ultimately, Rs. 1,03,013 annual recurring, and is debitable to the ordinary grants and heads of accounts affected. Further instructions will be issued showing how the expenditure likely to be incurred during the current year will be met and allocated to the several Divisions.

[37288 (Q.M.G.).]  
D.

A. H. BINGLEY, Major-General,  
Secretary to the Government of India.

#### APPENDIX I.

Terms of transfer for Veterinary Assistants now serving in the various branches of the Army in India, with the exception of those employed in the Army Remount Department, to the Veterinary Assistants' Branch of the Indian Subordinate Veterinary Corps.

<i>Silladar Cavalry.</i>	Status in Indian Subordinate Veterinary Corps.
Present Status.	
Senior Salutri with rank of Jemadar ...	Jemadar
Senior Salutri not holding rank of Jemadar ...	*1st class Veterinary Assistant
Salutri ...	*2nd or 3rd class Vety. Asst. according to length of service and date of qualification.

#### *Indian Mountain Batteries.*

Salutri ...	*2nd class Veterinary Asst.
*Provided they have graduated at an Indian Veterinary College.	

Salutri ...	3rd class Veterinary Asst.
If having undergone only a modified course at an Indian Veterinary College.	

#### *Supply and Transport Corps.*

1st grade Vety. Assistant ranking as Jemadar ...	1st class Veterinary Asst. (a)
(a) These Indian officers may elect for transfer to the Corps and will retain their present rank, and remain on their present terms of service, but will be eligible to be promoted to Senior Veterinary Assistants in the Indian Subordinate Veterinary Corps on passing the necessary qualifying examinations, etc., otherwise they will be included in the cadre of 1st class Veterinary Assistants, Indian Subordinate Veterinary Corps, but will be graded senior in that class.	
(If placed in charge of Transport Corps they will, in the Indian Subordinate Veterinary Corps, receive charge pay at Rs. 10 a month).	

2nd grade Vety. Assistant ranking as Warrant O.	2nd class Veterinary Asst. (b)
(b) These men may be transferred to the Indian Subordinate Veterinary Corps in the grade of 2nd class Veterinary Assistants ranking as Warrant Officers on pay of Rs. 75 a month and, when in charge of Corps, etc., will receive charge pay at Rs. 10 per mensem.	

3rd and 4th grade Vety.

Assistants ... 3rd class Veterinary Assts. (c)

(c) These men may be transferred to the Indian Subordinate Veterinary Corps in the grade of 3rd class Veterinary Assistant, ranking as Warrant Officers, on pay of Rs. 60 per mensem.

#### APPENDIX II.

Terms and conditions of service for the Veterinary Assistants' Branch of the Indian Subordinate Veterinary Corps.

The Veterinary Assistants' Branch will be divided into:—

**Indian Officers.**—Senior Veterinary Assistants—

1st class with rank of Ressaldar; 2nd class, with rank of Jemadar.

(The proportion of Indian officers will not exceed 10 per cent. of the total authorised establishment of the Branch, and will be equally divided between the two classes of Senior Veterinary Assistants).

**Indian Warrant Officers.**—Veterinary Assistants, 1st, 2nd and 3rd class.

The establishment of Military Veterinary Assistants will be maintained to fill:—

(a) Military appointments, viz., Class II Station Veterinary Hospitals, Indian Artillery, Indian Cavalry, Transport Units, Engineer Units, etc., with the authorised reserve of 25 per cent.

(b) Certain civil appointments, Imperial Service Troops, with the authorised reserves of 25 per cent.

**Recruitment.**—Military Veterinary Assistants will be recruited as far as possible from military students at Veterinary Colleges and Schools. Applications for admission to a Veterinary College as a military student will be made by the Officer Commanding the man's unit on India Army Form X-1835, to the Quartermaster-General in India through the General Officer Commanding Division, Divisional Area or Independent Brigade.

Military candidates for admission to the different Veterinary Colleges will be selected annually by the Quartermaster-General in India from the list of men submitted by the various regiments, services and departments, as laid down in paragraphs 61-68, Army Regulations, India, Volume VIII.\* Candidates must bear a good character, be physically fit for service, under the age of 25 years, be of the required educational standard and be recommended by the officer commanding their unit, who will satisfy himself that they will benefit by the instruction given at a Veterinary College or School.

Those who are selected and sign a declaration in the form annexed will be admitted to the Punjab Veterinary College, or other selected Veterinary College, or School, and entered as Indian military pupils to undergo a course of training for veterinary assistants. If they are reported qualified, they will be gazetted to the Indian

**NOTE.**—(i) All appointments to the Corps including transfer of temporary men should, during the period of the war, be considered as temporary, and not be made permanent until six months after the declaration of peace. In the meantime, men transferred to the new Corps will be placed in the various classes as shown above, and will take seniority in those classes according to the dates on which they graduated.

Future promotions will be governed by the terms and conditions of service shown in Appendix II.

**NOTE.**—(ii) All transfers are voluntary; but a man, once having elected transfer, will not be permitted to revert to his original terms of service.

\* These paragraphs are under revision.

Subordinate Veterinary Corps, graded according to the places they have taken at the final college examination, and assigned official numbers. The Director of Veterinary Services may remove from the College, and withhold the certificates of any pupil who fails at any examination, or misconducts himself. Military Veterinary Assistants will not be given their certificates until the close of their service, and should a man be dismissed or discharged for misconduct or inefficiency before completing seven years' service as a veterinary assistant, his certificates will be altogether withheld. Students gazetted into the Indian Subordinate Veterinary Corps may retain the books issued to them whilst in College or School, the selection of books to be retained being left to the discretion of the Principal of each College or School.

Examinations for promotions will be held annually under arrangements made by the Director of Veterinary Services.

The subjects for these examinations will be Regulations, Surgery and Surgical Applied Anatomy, Diseases of cattle, sheep, and camels, Medicine, Materia Medica and Hygiene. Promotion to the next grade will be withheld until all subjects in this examination have been passed.

When candidates fail in several subjects, or do very badly in one, the Director of Veterinary Services may direct that they shall not be permitted to re-appear at the next succeeding examination.

If well reported upon, Veterinary Assistants will be promoted as follows:—

- |   |  |
|---|--|
| (a) To Vety. Assistants, 2nd class          | } After 3 yrs. in 3rd and 5 yrs. in 2nd class, respectively—subject to passing examination mentioned above.        |
| (b) To Vety. Assistants, 1st class          |  |
| (c) Senior Veterinary Assistants, 2nd class | } By selection from Veterinary Assistants who have passed a post-grad. course at a selected Vety. Coll. or School. |
| (d) Senior Veterinary Assistants, 1st class |  |

A Veterinary Assistant degraded by sentence of a Court-Martial will, if restored to his former class, be re-examined, if he passed more than two years before his restoration. If not previously qualified, he may be examined at the same time as the subordinate above him.

Indian officers and warrant officers of the Indian Subordinate Veterinary Corps will take precedence as under:—

- Senior Veterinary Assistants, 1st and 2nd class, after senior Sub-Assistant Surgeons, 1st and 2nd classes.
- Veterinary Assistants, 1st class, after Sub-Assistant Surgeons, 1st class.
- Veterinary Assistants, 2nd class, after Sub-Assistant Surgeons, 2nd class.
- Veterinary Assistants, 3rd class, after Sub-Assistant Surgeons, 3rd class.

Veterinary Assistants in the Indian Subordinate Veterinary Corps will receive the following rates of pay, privileges and allowances:—

**Veterinary Assistants.**—Indian Warrant Officers.

3rd class	...	Pay Rs. 60	*Field allowance Rs. 5
2nd	"	" " 75	" " 10
1st	"	" " 95	" " 10

\* NOTE.—Field allowance (which includes cost of conveyance of baggage when marching by road) is admitted—

- (1) When travelling on duty, on field or foreign service, and while in camp on account of outbreaks of disease amongst military animals. The allowance is inadmissible while at or moving to or from camps of instruction.
- (2) When serving at Port Blair, Aden and Burma.
- (3) When attached to the Viceroy's Body Guard.

The minutes of the previous meeting having been published were taken as read and confirmed.

The Hon. Secretaries announced letters of apology for absence from Messrs. W. Freeman Barrett, T. McGuinness, H. Sumner, R. C. Trigger, W. Jackson Young.

#### REPORT.

The following report presented by the Hon. Secretaries was received and approved:—

Since the last quarterly meeting the following donations and new subscriptions have been received:—

Bolton's Cinema	£ 15 15 0
J. Holland (legacy)	100 0 0
W. Roots	10 10 0
Arnold Spicer	10 10 0
Eastern Counties V.M.A.	10 10 0
J. W. Knowles, Major U.S. A.V.C.	1 1 0

New subscribers:—

Anonymous (H. J.)	£1 1 0
Adamson, J., Major A.V.C.	1 1 0
Anderson, W., Capt. A.V.C.	1 1 0
Blampied, T. Le Q., Capt. A.V.C.	1 1 0

Wentworth, N. F.	1 1 0
Baker, E. Whitley (increase)	10 6

The amount of £100 has been invested in War Loan. We have been informed that the N.V.B. and M.D.S. has granted the sum of 7s. 6d. per week to Mrs. M. Johnstone for the twelve months ending August 1st, 1919.

We have been instrumental in arranging with the Ministry of Pensions for the payment of Officers' Pension direct to Mrs. McN., Case 31. No payment had been received since March of this year; and at last Mrs. McN. sought the good offices of the Fund.

#### THE CLEMENT STEPHENSON BEQUEST.

The Hon. Secretaries reported that under the Will of the late Dr. Clement Stephenson, a legacy of £5000, together with a share of the residuary estate, had been bequeathed to the Victoria Veterinary Benevolent Fund under the name of the Victoria Veterinary Benevolent Institution, London, provided that the Fund became incorporated within twelve months of the time of Dr. Stephenson's death.

It was resolved:

That the Council do gratefully accept Dr. Clement

Stephenson's Bequest of £5000 and share of residue, on the conditions attached.

That the necessary steps be taken to incorporate the Society under the Companies Consolidation Acts, 1908-1913, and that application be made to the Board of Trade for permission to omit the word "Limited" from the name of the Society.

That the draft Memorandum and Articles of Association submitted be approved, subject to any alteration required by the Board of Trade and/or the Registrar of Joint Stock Companies.

#### CASES.

Applications numbered 39, 40, 41 and 42 were considered, and it was resolved:

That no grant be made in cases 39 and 42.

That Case 40 be deferred, there being no indication of present necessity.

That the President and Treasurer be requested to make further enquiries in Case 41, and if necessary they be empowered to make a grant not exceeding 10s. per week.

*Renewal of Grants.* The President and Treasurer were empowered to increase the grants made in the most necessitous cases by 50%, and to continue the other grants at the same rates as hitherto. A special grant of £2 was made in case 27 (widow, aged 81) for the purchase of coal or other comforts.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

Wm. E. Blackwell, Capt. A.V.C.	£1 1 0
Thos. H. L. Duckworth, Ashbourne (1917, 1918)	2 2 0
Edward Kitchin, London, E.C. (1914-15-16-17-18)	5 5 0
G. P. Male, Reading	1 1 0
Robt. E. Murison, Capt. A.V.C.	1 1 0
F. T. Prince, Ashbourne (1917, 1918)	2 2 0
W. Dunlop Smith, D.S.O., Lt.-Col. A.V.C.	1 1 0
Eric Wallace, Capt. A.V.C.	1 1 0
F. W. Watchorn, Newtown, Montgomeryshire	1 1 0
Previously acknowledged	1052 3 11
	£1067 18 11

#### The "New" Rabbit Disease.

To the Editor of the Times.

Sir,—In your issue of to-day there is a paragraph entitled "Warning to Rabbit Keepers," stating that a disease, believed to be due to a form of "fluke," has recently appeared over a wide area. It is said that the rabbits die suddenly, without outward symptoms, and that the disease is caused by eating wet greenstuff.

So far as I am aware, rabbits do not suffer from "fluke" disease. Occasionally wild rabbits have been found in which specimens of the common sheep fluke have occurred, but these are wholly exceptional cases. The mode of spread of this parasite is such that there is little likelihood that it could ever attain notoriety in the hutches of suburban rabbit-breeders.

In the liver and among the coils of the gut of rabbits one not infrequently finds small white cystic bodies, varying from the size and appearance of a rice grain to that of a mistletoe berry. These are often mistaken for "flukes," but are actually the developmental stage in the rabbit of the tapeworm of the dog. Offal from rabbits

infected with these cysts should not be fed to dogs. The present serious outbreak is *not* due to worm parasites, but that young tame rabbits are dying in numbers from an intense enteritis set up by a microscopical protozoan parasite (*Eimeria stiedii*) which invades the gut wall, and almost completely denudes the absorbing surface. The disease is very fatal to the young, but old rabbits can harbour the infection without showing definite symptoms. It is spread by resistant cysts passed in the excrement of an infected animal. An apparently healthy but infected doe may thus produce a litter in which there is a heavy mortality.

Preventive measures consist in the destruction or isolation of infected animals, and the careful periodical removal of all excrement. If there is danger from eating wet greenstuff, this is probably due to the fact that dry, powdery excrement, containing the infective cysts adheres much more rapidly to wet than to dry surfaces.

Rabbit-keepers should clearly realise that this disease is brought into the hutch and is spread there by an infected, though not necessarily sick, animal, and not by greenstuff. Whether or no an animal is suffering from the infection can be readily determined by a microscopical examination of a pellet of excrement. Man is susceptible to infection, but few cases of the disease are on record.

#### Bismuth Iodiform Paraffin Paste in injuries to bones.

Writing to *The British Medical Journal*, E. H. Walker, M.B., B.S.LOND., M.R.C.S., Captain R.A.M.C. (T.C.), says:—

"The following is the method of treatment which I now adopt in bony injuries, whether recent or chronic, for it is bony injuries in which this treatment gives particularly successful results compared with other methods.

First, the wound edges are excised; secondly, a free incision is made and loose fragments of bone and foreign bodies are removed; thirdly, the wound is well dried with gauze; fourthly, methylated spirit is swabbed over the wound, and, finally, with the wound as dry as possible, B.I.P. is well rubbed into the surface; a teaspoonful is usually sufficient. The wound is then lightly packed with dry gauze, and dry gauze is placed over the surface.

The following day I usually change the surface gauze, as there may be a little oozing. Then, provided the gauze packing keeps dry, it can be left in for at least a week.

If it becomes very moist with discharge I take it out and mop up the discharge with a dry swab (in contradistinction to bathing it with a wet solution), and then repack it occasionally, gradually allowing the wound to close up.

I do not intend to discuss the pathology, as this has been done by Dr. L. G. Anderson (*Lancet*, March 3rd, 1917), but there are a few points to which I should like to call attention.

Firstly, the reason I emphasize keeping wet dressings away from the wound is because these leave a fluid residue which wets the gauze packing, and is thus apt to give a false impression of the amount of discharge; it also washes out some of the B.I.P.

Secondly, I consider that forcible syringing of deep wounds, especially if they are not carefully dried afterwards, is a very common cause of pocketing and spread of infection along the lines of least resistance. If B.I.P.

is used as described above, I feel sure that many secondary operations for establishing drainage will be avoided.

Finally, in cases undergoing this treatment, an enormous amount of redressing would be avoided, resulting in a great economy of dressings and of time and labour. In addition to this, the patient will benefit by less frequent dressing."

#### ARMY VETERINARY SERVICE

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Oct. 11.

##### REGULAR FORCES. ARMY VETERINARY CORPS.

Temp. Lt. to be temp. Capt.:—F. Christopher (Aug. 13).

Temp. Hon. Lt. (temp. Capt.) H. A. Crowe to be temp. Maj. while holding a special appt. (Cl. B.B.) (Feb. 25).

Oct. 12.

Maj. (Bt. Lt.-Col.) P. J. Harris, relinquishes the actg. rank of Lt.-Col. on ceasing to hold the appt. of Asst. Dir. of Vety. Servs. (Aug. 16).

Oct. 14.

To be temp. Lt.:—N. Macleod (Sept. 17).

Capt. A. A. Pryer, D.S.O., Dep. Asst. Dir. of Vety. Servs. (Cl. FF.), ceases to be graded for pay (Cl. FF.) (Aug. 21).

Temp. Qmr. and Lt. W. H. Mawdsley, to be Capt. under Art. 330, R. Wt. for pay and promotion (Oct. 1.)

##### TERRITORIAL FORCE, ARMY VETERINARY CORPS.

Oct. 10.

Capt. W. K. Townson relinquishes his commn. on acct. of ill-health contracted on active service, and is granted the hon. rank of Capt. (Oct. 11).

The following casualty is reported:—

DIED—Capt. R. B. Cockburn.

#### Animal photographic portraiture.

We sometimes smile at the old drawings and steel engravings which depict animals with amazingly well-balanced bodies, generally set on quite impossible legs. We make allowances for drawings and paintings, and we try to find out whether reliable contemporary observers of the wonderful animals left word-portraits. Amos Cruickshank's concise and plainly homely picture of Lancaster Comet has caused smiles in many quarters—"He was made and put together like a fat pig"—but it was remarkably effective, as the older breeders in the North can testify.

It was wont to be said that the camera cannot lie, but the camera in the hands of an expert is fit to give any number of points to all the ordinary disciples of Ananias and Sapphira. The camera ought not, perhaps, to be held responsible for the faking of negatives, but in any case it is associated with things which make the delicious gripe. When dealing with such breeds as the Shorthorn, Aberdeen-Angus, Hereford, and Highland, the common photographic temptation is to represent the animals as mathematically straight above and below, and perfectly balanced fore and aft. The thing tends to become a front-rank nuisance. It is artistic impertinence. Nature avoids mathematically straight lines such as we see in many drawings and in some much lauded photographs. The actual departures from the straight and approximately square are sometimes

very slight, as in the case of the Shorthorn Flora 6th or the Highland Fuirery Queen, and from the cylindrical as in the Aberdeen-Angus Everwise, yet the something which is infinitely better remains.

But is an artist not entitled to make the best of his model? He should represent his model at its best, if he can. That is an entirely different matter. Many years ago, when I was writing an article on Highland cattle for a somewhat important publication, I was offered a photo of a bull, taken from a painting by a famous artist. I did not accept it. Was it not good enough? It was by far too perfect. The animal might have been made in the foundry.

Great pressure is frequently put on photographers to produce what are termed high-class portraits. Owners want something better than the truth. I should go so far as to say, Let them have the truth in love, or the veracities mainly on the sunny side. Photography ought to be of great historic value. As now practised by many I am afraid it is storing up for itself things which will furnish caustic verdicts in future days. May I repeat that I like to see animals "well taken," but they must be the real animals, not dandified caricatures.—JAS. CAMERON, in *Live Stock Journal*.

#### WIND AND WATER.

The following little incident I heard in a store in a small town in the South of Ireland a few days ago. I call the place a store, but in reality it is a public house. The licensing laws differ somewhat in this part of the United Kingdom (anyhow at present!) They sell nearly everything from ale to Zambuck.

A carrier came in one morning for his usual "half-un" and wanted another "weight" (21lb.) of potatoes. The woman of the house knowing the man and his establishment asked him what he did with the potatoes he was getting, as he had had seven weights. Well, he said, I give them raw in the morning to the horse for his wind and in the evening I give them boiled for his water.

No. 1581

OCTOBER 26, 1918.

VOL. XXXI.

## THE ANNUAL REPORT OF THE CHIEF VETERINARY OFFICER TO THE BOARD OF AGRICULTURE: 1917.

The Annual Report, as usual in these days, is brief and condensed; but it is eminently business-like, and reports a great amount of work.

The longest and most detailed section, which is also the most interesting and important, is that upon Swine-fever. This is almost wholly concerned with the results of serum treatment during the period from October, 1916 to September, 1917, and is very valuable. Records were kept of outbreaks in which serum was used, and of others in which for various reasons it was not; and the report compares the results in "serum" and "non-serum" outbreaks with considerable detail. The figures speak well for serum treatment. In the serum outbreaks, as compared with the non-serum, there were substantial decreases in the death-rate and number of pigs killed for food respectively, with a corresponding increase in the number of pigs freed. The birth-rate during the isolation period in serum outbreaks was more than double that in non-serum outbreaks. Evidently serum treatment is succeeding; and owners appear to have realised this even in 1917, for we read that "the proportion of suitable cases (*i.e.*, cases in which it was not certain that infection had already spread to all the pigs) in which serum was accepted was 80.5 per cent." The most unsatisfactory feature of serum treatment at present is the number of cases in which, for one reason or another, it cannot be adopted. In 564 cases (more than 20% of the outbreaks during the period) it is stated that "conditions were unsuitable for treatment;" while in no less than 220 of the 2531 outbreaks in the year the position was that "no pigs remained alive on the premises for treatment at the completion of diagnosis." This last condition suggests the old trouble—the delay in reporting; which doubtless also had much to do with the 564 cases in which "conditions were unsuitable." Obviously, unless this can be remedied, serum can never give anything like its maximum results.

Some of the details regarding glanders are of interest. There were 25 outbreaks in the year, involving 63 affected animals; and the total number of animals on infected premises was 470. Of the 63 affected animals, 19 were clinical cases, and the remaining 44 were detected by mallein. These 44 reactors amounted to 9.7 per cent. of the animals tested; and 11 of these, or exactly a quarter, only gave a definite reaction to the second test. It is noteworthy that no less than 6 of the 25 outbreaks occurred in horses engaged in colliery work, and 2 of these were discovered through the operation of the Mines Act, which is doing much good against

glanders. As 12 outbreaks occurred in London and the adjoining counties of Essex, Kent, and Middlesex, this leaves only 7 outbreaks in the rest of Great Britain, except those in the colliery horses.

Not very much is said concerning anthrax; but what does appear is interesting. It is noticeable that over 80% of the outbreaks occurred on premises which, so far as was known, had been previously clean. The tabulated results of inquiries as to the probable source of origin in these are published, and cast great suspicion upon the use of imported food-stuffs and artificial manures of animal origin, especially the former. This is by no means the first evidence we have had tending to incriminate imported food-stuffs in particular; and its frequent occurrence is more than suggestive. Another important, and a very unsatisfactory point is the number of cases, amounting to about 15 per cent. of affected animals, in which the disease was not reported until the carcasses were "caught"; as it were, at knackers' yards or slaughter-houses. This is an old difficulty, which does not seem to lessen as time goes on. As the Chief Officer remarks, it "calls for firm action by the Local Authorities when cases are brought to light."

The section upon sheep-scab is mainly concerned with details regarding the transmission of the disease between the different countries in the United Kingdom. A table is given showing the proportion of outbreaks in England attributable to infection from Scotland, and shows that, as in 1916, we imported disease from Scotland to a serious extent.

Here it is satisfactory to note that the local regulations imposed in Cumberland, which require double-dipping of all sheep arriving at farms from Scotland, have proved a success in that county; this supports the Board's view, expressed in the last annual report, that the measure is the best guarantee against the importation of infection. Wales remained seriously infected during 1917, but did not cause many outbreaks; and the 9 outbreaks which did occur were confined to the counties bordering upon the principality. The number of cargoes from Ireland which contained affected sheep was decidedly higher than in 1916. In connection with this disease we should remember that this year the figures, up to the present, are much better than those for 1917.

Hardly anything is said of parasitic mange, beyond the remark that, "owing to war conditions," it has shown a tendency to spread. It certainly has; and the tendency has become much more manifest since the expiration of the period under report, doubtless from the same cause.

Very little is said of the other work at the Board; but it is noted that the Laboratory issued 43,290 average doses of anti swine-fever serum, and 14,560 doses of anti-abortion vaccine, which speaks well for the popularity of the Board's vaccine therapy. Altogether the report is an interesting summary of a years good work, and is well worth the small cost of two-pence to practitioners.

## AVIAN DISEASES.

This week we reprint the concluding portion of a long report upon an outbreak of Fowl Typhoid, the preceding portion of which appeared in our issue of October 5. It is taken from the *Journal of the American Veterinary Medical Association*, and was presented at the Annual Meeting in September, 1915: we have given it here almost in full—some tables and details are omitted, but there is sufficient to show the amount of work that was put into the investigation. It was carried out at one of the many State Experiment Stations in U.S.A., and though it cannot be said that such reports are common there, they are not infrequent in connection with avian diseases. In French and other continental journals, too, pathological notes have been fairly frequent during the last 25 years—and were by no means unknown earlier.

There are two main reasons which probably account for the neglect of diseases of the smaller domesticated animals, including fowls, in this country for the last hundred years. One was, and in a measure is still, the high value of the horse, as well as of pedigreed cattle. The other, the abominable neglect of our agriculture as a national asset by successive governments.

The supersession of the horse by motor traction was the means of turning the attention of many of our veterinarians to the diseases of the dog and cat, men who had previously declined to trouble themselves with such cases. There are still men in practice—not old men at that—who will not, or cannot, get beyond the old faiths. At the present time there are "Poultry Experts" attached to various institutions who, presumably, undertake what veterinary work is required; and some who supply instruction and advice through the columns of the "weeklies."

## THE L.G.B. AGAIN.

Our readers will notice that under the heading of "Clean Milk Supply," in report of meeting of Council R.C.V.S., the testing of cattle with tuberculin may be placed under control of the Local Government Board: and that a letter has been submitted on the question. It is not the first time that cattle diseases have been claimed as falling in the domain of the L.G.B.

## Royal College of Veterinary Surgeons.

## SPECIAL MEETING OF COUNCIL.

A Special Meeting of the Council was held at the College, 10 Red Lion Square, London, W.C.1, on Friday, October 18th, when the following members were present: Mr. F. W. GARNETT, President, in the Chair; Maj. J. Abson, Mr. G. A. Banham, Maj.-Gen. L. J. Blenkinsop, Mr. J. C. Coleman, Sir John M'Fadyean, Mr. S. H. Slocock, Sir Stewart Stockman.

The minutes of the previous Special Meeting of Council were read and confirmed.

The SECRETARY announced that he had received apologies for absence from the following members:—Messrs. Bradley, Clarkson, Dunstan, Lawson, McKinna, Mulvey, Price, Thompson, Trigger, Wilson.

On the motion of Sir Stewart Stockman, seconded by Sir John M'Fadyean,

It was resolved: That the following alteration to Bye-law 80, passed at the previous special meeting, be confirmed, and that the seal of the College be attached thereto:—

"Each candidate for the office of Examiner shall, at least fourteen days before the election, intimate in writing to the Secretary his willingness to be appointed, and submit with his application a statement of his qualifications." The remainder of the Bye-law to stand as at present.

*Linseed Oil supplies.* A letter was received from the Chairman of the United Kingdom Linseed Oil Consumers' Association stating that the scheme of distribution had not yet been settled, and that a further communication would be sent in due course.

*Mettam Appeal.* A copy of an appeal for a Civil List Pension to be granted to Mrs. Mettam was received, and

It was resolved: That a Special Committee consisting of: The President, Maj.-Gen. L. J. Blenkinsop, Sir John M'Fadyean, and Sir Stewart Stockman be appointed with power to take such action in support of the appeal as they may think necessary.

*Clean Milk Supply.* A draft letter to the Ministry of Food was submitted, pointing out that the testing of Cattle with Tuberculin is a veterinary matter which should be under the control of the Board of Agriculture and Fisheries, and not of the Local Government Board. The draft was approved and ordered to be transmitted to the Ministry of Food, a copy to be sent to the Board of Agriculture and the Local Government Board.

## THE VETERINARY TRIBUNAL.

A meeting of the Veterinary Tribunal was held at 10 Red Lion Square, London, W.C.1, on Friday, 18th inst., when the following members were present:—

Mr. F. W. Garnett, Chairman; Messrs. G. A. Banham, H. J. Dawes; Sir John M'Fadyean; Messrs. S. H. Slocock, J. Willett, W. Woods.

The following cases were dealt with:—

GREENWAY, Edward, Prospect House, Church Street, Frodsham. Age 30. Category A. N.S.R.'s application allowed. Man not to be called up till 18th Nov., 1918.

HOLROYD, J., 1 Simmons Street, Blackburn. Age 30. Grade 3. Temporary exemption allowed for six months, to 18th April, 1919.

CORMACK, J. L., 38 Holyhead Road, Coventry. Age 31. Grade I. Temporary exemption allowed for three months, to 18th January, 1919.

HUNTING, C. S., 16 Forest Road, Loughborough. Age 31. Grade I. N.S.R.'s application allowed. Man not to be called up till 18th November, 1918.

FORREST, R. L. C., Carlisle House, Towcester. Age 33. Grade I. Man's application refused. Not to be called up till 18th November, 1918.

LAYCOCK, H. R., 64 Fitzwalter Road, Sheffield. Age 33. Grade I. N.S.R.'s application refused. Conditional exemption granted, to remain.

SEARBY, B. A., Ramsey, Hunts. Age 34. Grade I. N.S.R.'s appeal refused. Conditional exemption granted to remain.

JONES, J. R. A., Russell Street, Gloucester. Age 30. Category A. N.S.R.'s application refused. Conditional exemption, to remain.

TRIGGER, William, Queen Street, Newcastle, Staffs. Age 35. Grade B1. Temporary exemption allowed for three months, till 18th January, 1919.

STANLEY, P. A., 15 College Avenue, Tavistock. Age 38. Grade I. Temporary exemption allowed for three months, till 18th January, 1919.

MUNBY, J. C., 21 Cliffe High Street, Lewes. Age 42. Grade I (B1). Temporary exemption granted for three months, till 18th January, 1919.

SUGDEN, F. H., Stanton House, Grantham. Age 40. Grade II. Temporary exemption granted for three months, till 18th January, 1919.

HUDSON, R., 29 Bridgegate, Retford, Notts. Age 42. Grade II. Temporary exemption granted for six months, till 18th April, 1919.

BRITTAI, H. A. G. K., 16 Redcar Road, Guisborough. Age 41. Grade II. Temporary exemption granted for three months, till 18th January, 1919.

THOMPSON, F., 4 Northumberland Street, Morecambe. Age 51. Grade II. Temporary exemption for six months, till 18th April, 1919.

CONCHIE, J. W., 30 Station Hill, Kidderminster. Age 41. Grade III. Temporary exemption for six months, till 18th April, 1919.

HOWE, A. B., Cromford Road, Wirksworth, Derbyshire. Age 43. Grade III. Temporary exemption granted for six months, till 18th April, 1919.

WYNNE, J. H., Tan y Craig, Denbigh. Age 49. Not examined. Man's application allowed. Temporary exemption granted for six months, till 18th April, 1919.

NIXON, S. H., 91 Wicker, Sheffield. Age 36. Grade II. N.S.R.'s application refused. Temporary exemption granted for six months, till 18th April, 1919.

CUNDELL, F. H. W., 30 Marlborough Road, Swindon. Age 40. Grade I. N.S.R.'s application refused. Temporary exemption granted for six months, till 18th April, 1919.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

**A REPORT UPON AN OUTBREAK OF FOWL TYPHOID.**  
By WALTER J. TAYLOR, Assistant Professor of Veterinary Science, College of Agriculture, University of California.

(Concluded from p. 108).

In order to ascertain the period of incubation, study the clinical symptoms of the disease, carry on some inoculation experiments and verify our pathological findings, we secured a number of fowls of various breeds from a local poultry supply house.

Inasmuch as this disease had been described as affecting the normal blood content, the examination of the blood was begun as soon as the experimental birds were inoculated. The results of these examinations were as follows:—

Table No. I. (Abridged).

Experimental Fowl No. 1. White Leghorn Cockerel.

	Temp.	Red Cells.	Leucocytes.
Aug. 8	108.1	3840000	20220
Injected 1 c.c. 30 hour bouillon culture in wing vein at 6 p.m.			
10	109.4	3332000	35600
	Diarrhoea present.		
14	107	2592000	89440
21	106.4	2924000	51280

At this date we learned that this bird had been fed viscera from a fowl out of the affected flock a couple of weeks before.

This bird was in apparently perfect health at the time it was killed and a post-mortem examination made. (Aug. 29). The only pathological lesion found was a slightly enlarged and dark coloured liver. Cultures were made on slant agar from the spleen, liver and kidneys. A pure culture of the organism under observation was obtained from the spleen. The tubes inoculated from the liver and kidneys remained sterile.

Plate cultures in series made from the rectum showed, among many others, probably colon, several colonies resembling those of the organism causing fowl typhoid. From one of the colonies, *Bacterium sanguinarium* was recovered and was shown by the cultural characteristics and the morphology.

[Four other experiments are quoted with temperature and blood counts as in No. 1. One was inoculated with bouillon culture—died 11th day. One, fed spleen and portion liver from previous bird—recovered. Two, fed cultures of *B. sanguinarium*, each died on 8th day. Tables of differential leucocyte counts are given].

The tables show that the increase in leucocytes is confined almost entirely to the polymorphonuclear variety which of course affects the total percentage of the other varieties.

In view of the fact that our findings differ somewhat from those of Moore and Dawson, we give below what we found to be the morphological, cultural and biochemical properties of *Bacterium sanguinarium*.

**Morphology.** The individual organisms are short rods with rounded or somewhat pointed ends. They usually occur singly but in clumps or masses from tissue, while in culture they may appear in pairs united end to end. In size they vary from .3 to .5 microns broad and 1 to 2 microns long. There seems to be a peripheral arrangement of the protoplasm observed when stained with fuchsin or methylene blue. This is especially noticeable in smears made from diseased tissue. It is Gram negative.

**Cultural and Biochemic properties.** The organism is aerobic and facultative anaerobic. It grows readily at from 34 to 37.5 degrees centigrade, somewhat less vigorously at room temperature.

Results are also given on Plain bouillon, Sugar-free bouillon, Agar, Gelatin stab, Milk, Litmus milk, Potato, Egg medium.

**Action on sugar.** *Dextrose.* There is uniform cloudiness throughout the tube in 24 hours. The reaction is acid but no gas is formed. On further incubation the acidity becomes more pronounced but no gas is formed even at the end of 72 hours.

*Lactose.* A slight cloudiness appears in the open arm and curvature of the tube in 24 hours although the closed arm remains perfectly clear: no gas is formed. The reaction is slightly alkaline, becoming more alkaline upon further incubation, with slight sediment.

*Saccharose.* A very slight cloudiness appears in the open arm of the tube in 24 hours: the closed arm is clear. No sediment occurs: the reaction is at first

neutral becoming alkaline in 72 hours: no gas is formed.

**Resistance of the organism.** The action of direct sunlight upon the organism destroyed it in 25 minutes. It will live for 32 hours in the dark in the dried condition. It is killed by a temperature of 60° C. in ten minutes.

A 3% solution of phenol destroyed it in 8 minutes.

**Inoculation Experiments on other animals.**  
**Guinea Pig.** A female guinea pig of 460 grammes weight was inoculated per sub cutem with .3 c.c. of a rich bouillon culture of *Bact. sanguinarum* on Aug. 15 and was found dead at 8 a.m. on Aug. 20. The organism was recovered from the tissues.

During the past few years quite a little attention has been accorded to a disease of fowls which although primarily being studied as a disease of young chicks is now recognised as affecting adult fowls. This disease is known under the names of bacillary white diarrhoea in chickens and also as fatal septicæmia of chickens. In 1908 Rettger and Harvey published their findings upon the study of this disease and announced the discovery of an organism which they named *Bacterium pullorum*. In 1912 Jones reported finding this organism in a fatal outbreak of disease in adult fowls. Since Jones reported his findings it has become a well established fact that young chicks which have recovered from this disease may harbour the germ and when mature transmit it through their eggs as adult fowls.

Because of a similarity to a certain extent of the morbid anatomy in the disease caused by *Bacterium sanguinarum* and that produced by *Bacterium pullorum* in adult fowls, we give a comparison of the morphology, cultural, biochemic properties, and the resistance of the two organisms. [Table omitted.]

#### SUMMARY.

A careful review of the work done by us during our investigation of this disease would warrant the conclusion that we were dealing with the disease described by Moore in 1895 as Infectious Leukemia, confirmed by Dawson in 1898, and studied as Fowl Typhoid by Curtice in 1902.

We have found that there are certain differences observed by these writers to which we wish to call special attention. Moore states that "diarrhoea is not present," while Dawson observed that "there is a profuse diarrhoea."

In the same way Dawson describes the organism as "coagulating milk in one day," while Moore announced a "saponification of milk after a period of incubation" and no coagulation.

During our experiments and as described by the owner in the outbreak resulting in the investigation, diarrhoea was present in about 80% of the cases. Again, we have found the organism to saponify milk in four to five weeks while no coagulation occurred.

Moore has called attention to the fact that examination of the blood of a diseased fowl, Toisson's fluid being used as a diluting agent, showed that numerous red corpuscles appeared to take the blue stain more or less intensely. Ward, in his bulletin on fowl cholera, draws attention to certain cells not leucocytes, taking the blue stain and described at some length the morphology of these cells. Undoubtedly Ward was describing what latre Warthing designated as "thrombocytes." Burnett has called attention to these cells and describes them as being "undoubtedly the result of degeneration."

During the work just completed on this disease, we wish to corroborate the findings of Moore. In making examinations of the blood of diseased fowls, using Toisson's fluid as a diluent, we have found in every case red cells showing all the characteristics of a normal red blood cell of healthy fowls, except that they were stained more or less intensely blue. As many as nine of these cells have been observed within the 9 sq. mm.

ruled space of the Zappert-Ewing counting chamber. The so-called thrombocytes were also noted and compared as to morphology drawn. We have not found these blue stained red cells in examining the blood of normal fowls.

#### CONCLUSIONS.

A study of the work done by us seems to justify the following conclusions:

1. Fowl typhoid is a specific disease of fowls caused by *Bacterium sanguinarum* occurring sporadically and causing heavy losses among affected flocks; and unless properly investigated may easily be mistaken for fowl cholera because of its high mortality.

2. The specific morbid conditions consist of an enlarged liver containing necrotic areas, an enlarged spleen and a general anæmic condition of the serous and mucous membranes together with a marked increase in leucocytes and a corresponding decrease of the red cell content of the blood.

3. The increase in leucocytes seems to be confined to the polymorphonuclear variety.

4. Fat, well-conditioned, adult fowls are more susceptible than young, nearly mature growing birds.

5. Birds may contract the disease by the ingestion of pure cultures of *Bacterium sanguinarum*.

6. Birds fed upon the offal of other birds dead of this disease show a mild non-fatal form of the disease, tending to recovery.

7. There is evidence that recovery from this mild form produces more or less of an immunity. Further investigations upon this point is needed.

8. The power of some of the red corpuscles of the affected fowls to take the violet stain, when the blood is diluted in Toisson's fluid is especially noticeable in this disease.

9. While the lesions produced in fowls which are infected with *Bacterium sanguinarum* resemble in many respects those produced by *Bacterium pullorum*, and although there is a still closer resemblance in the biological characters of the two organisms, there is enough difference to warrant the conclusion that they are distinctly different diseases.

[A list of works referred to is given, six of which are Bulletins, or reports of work at Agric. Expt. Stations.]

#### EXTRACTS FROM DISCUSSION.

Dr. K. F. Meyer: Through the courtesy of Dr. Haring I was able to autopsy, the following year, some of the fowls from the same flock, and I was able to isolate the same organism and to corroborate his findings. We were vitally interested in this organism from the viewpoint of its relation to the typhoid bacillus and to other organisms, and our work was in progress when a publication appeared in which practically all the conditions which we intended to investigate were already thoroughly discussed, namely, this bacillus of fowl typhoid is closely related to the *Bacillus typhosus*. It is gratifying to find others who support us. We were able to agglutinate this organism very satisfactorily.

Dr. Christiansen: In the first place it is not generally supposed that typhoid is able to exist in the body of a chicken. Statements have been made, I believe, as to the length of time required for the body of a chicken to rid itself of the typhoid. We found that certain strains of typhoid are much more pathogenic in some chickens than in others. Working with the infected strain we found we could recover the typhoid from the blood of a chicken eight hours after inoculation. Furthermore, after nine hours inoculation, the chicken was dead, but whether or not that was due to shock or whether it was due to the toxicity of the typhoid, we are not able to state.

Another interesting observation is that the agglutination of the typhoid, or rather the conglutination of the

various strains of fowl typhoid, differ from ordinary typhoid serum. For instance, we find that a rabbit immunised with the army and navy strain was protected against a lethal dose of fowl typhoid organism.

These experiments we hope to have recorded in the near future.

Dr. Eichhorn: I think it would be of interest to mention the experiments which are now being carried out in the pathology division of the Bureau of Animal Industry with the *Bacillus pullorum*—as to its diagnosis in chronic cases. The preparation used is somewhat similar to that for the diagnosis of tuberculosis, but of course it represents only a product of the organism. The intradermal test of a chicken is made and the reaction is somewhat similar to the tubercular reaction in fowls. The results are not conclusive but are very promising, and aim to make possible the determination of the disease in its chronic form when usually the ovaries are affected, and in that way separate the diseased animals from the healthy flock and prevent subsequent infections.

#### THE CENTRAL VETERINARY SOCIETY.

[NATIONAL V.M.A.—SOUTHERN BRANCH.]

The Annual General Meeting was held at 10 Red Lion Square, London, W.C., on Thursday evening, Oct. 3rd. The President, Prof. G. H. WOOLDRIDGE, occupied the chair, and the following Fellows were present:—Messrs. W. Roger Clarke, H. D. Jones, J. W. McIntosh, H. J. Parkin, S. H. Slocock, E. L. Stroud, W. N. Thompson, J. Willett, and Hugh A. MacCormack, Hon. Sec.

On the motion of Mr. Willett, seconded by Mr. McIntosh, the minutes of the last annual general meeting were taken as read and confirmed.

*Correspondence.* It was announced that letters regretting their inability to attend had been received from Mr. N. Almond and Mr. T. Salusbury Price, and also a telegram from Maj. W. S. Mulvey.

Mr. H. H. Whitlamsmith wrote, tendering his resignation as a Fellow of the Society, and it was unanimously decided that the Hon. Secretary should write to Mr. Whitlamsmith saying that the President and Fellows regretted the decision at which he had arrived, and hoped he would reconsider it.

#### ANNUAL REPORT AND BALANCE SHEET.

The Hon. SECRETARY presented the following annual report:—

Mr. President and Gentlemen,—The Council are pleased to be able to announce that though we are still going through arduous times, the session 1917-18 has been a successful one. Two Fellows have been elected, and one has resigned. The annual meeting was held in October, at which Prof. G. H. Wooldridge was unanimously elected President. Five ordinary, one special, and two Council meetings have been held, with an average attendance of 15 at the ordinary meetings.

In previous years we have had monthly meetings from October to July, but it was thought better last session, as so many of our Fellows are doing military duties, and considering the great stress of the times, to have meetings only in alternate months.

It was decided not to have an annual dinner till more propitious times.

The following papers were read:—Capt. J. Malcolm Armfield, A.V.C., "A few diseases affecting animals in Northern Rhodesia." The paper was exceedingly interesting as most of the diseases described were tropical—quite new to the Fellows. The President, Prof. G. H. Wooldridge, gave a paper on "Acne and Impetigo," in which he dealt fully with the subject.

In January a special meeting was held at which Mr. H. D. Jones read a paper on "The rationing of horses; and some of its ill-effects due to insufficient and inferior food." The subject was well discussed. Letters, embodying the resolution passed at the meeting were sent to the Hay Controller, and to the Horse Food Controller, with satisfactory results. At the May meeting Mr. G. H. Livesey, brought forward the following proposition: "To consider the position of Veterinary Surgeons under the new Military Service Act." After giving the matter great consideration, it was decided to communicate with the Minister of National Service, and enclosing resolution passed; copies were sent also to the President of the Royal College of Veterinary Surgeons.

In response to a letter from Mr. Leslie Scott, Q.C., M.P., we discussed the question of "The feeding of horses in relation to their ability to perform their work, and the prevention of cruelty." The resolution was embodied in a memorial which Mr. Leslie Scott presented, at the head of the deputation to the Home Secretary; who was accompanied by the Commissioner of Police and the Horse Food Controller. Some improvement in the conditions resulted therefrom.

We have to thank the following Fellows for exhibiting post-mortem specimens: Prof. G. H. Wooldridge, Messrs. W. Perryman, H. D. Jones, and F. W. Willett. We hope this session that we will have a larger number brought forward. Specimens are always interesting and instructive.

The Council desires again to make a special appeal to Fellows still remaining at home, and would urge them to endeavour to put in a more regular attendance at the meetings and thus help the Society to carry on its useful work during the war.

The balance brought forward and the receipts for the year amount to £99 10s. 7d.: the expenses were £53 1s. 6d.: leaving a balance of £46 9s. 1d.

*The Balance Sheet.* The Hon. TREASURER, Mr. E. L. Stroud, in response to a suggestion from the President, that he might wish to make some remarks on the balance sheet, said he thought that, considering the times the country was going through, the balance sheet was very satisfactory. The Society had been able to pay its way, and there was a fair balance in hand at the bank.

The PRESIDENT remarked that the balance sheet showed that the Society's funds had increased by £2 8s. 8d. during the past year, the balance brought forward from the previous year being £44 0s. 5d, and the cash at bank and the Treasurer's hands at the end of the year being £46 9s. 1d.

Mr. WILLETT, in moving the adoption of the report and balance sheet, thought the Society had every reason to congratulate itself on having been able to carry on and to pay its way considering the strenuous year through which it had passed.

Mr. THOMPSON seconded the motion, which was carried unanimously.

#### ELECTION OF OFFICERS.

*President.* The Hon. Sec., in moving the re-election of Prof. G. H. Wooldridge for the forthcoming year, said that not only the Council, but several Fellows by whom he had been approached were unanimous in their desire that Prof. Wooldridge should be re-elected to the position he now occupied. Prof. Wooldridge knew the ropes of the Society to the finger-tips; under his presidency the Society had done remarkably well during the past year, and he was sure the Fellows could not do better than re-elect him. (Hear, hear).

Mr. WILLETT formally seconded the motion, which, on being put to the meeting by the Hon. Secretary, was carried with acclamation.

The PRESIDENT, who was received with applause, said it afforded him much pleasure to accept the honour

the Fellows had again conferred upon him, and with their assistance he hoped that during the forthcoming year the Society would be able to do as good work as it had done in the past. Its actions had not always met with favour, and sometimes it had got mildly called over the coals by the Royal College of Veterinary Surgeons, but the Fellows did not mind that, because they thought it might have done some good in making the College take further action.

**Vice-Presidents.** On the motion of Mr. Willett, seconded by Mr. McIntosh, Messrs. N. Almond, G. H. Livesey, W. Roger Clarke and J. B. Buxton, were unanimously re-elected Vice-Presidents.

**Council.** On the motion of Mr. W. Roger Clarke, seconded by Mr. E. L. Stroud, the Council, consisting of the following gentlemen, was also unanimously re-elected: Messrs. R. J. Foreman, H. D. Jones, J. W. McIntosh, F. G. Chamberlain, W. S. King, W. N. Thompson, J. Willett, H. King, W. R. Davis, H. J. Parkin, and F. W. Willett.

**Hon. Treasurer.** The PRESIDENT, in moving the re-election of Mr. E. L. Stroud as Hon. Treasurer, said that that gentleman had acted so excellently in that capacity for so many years past that no encomiums were required to urge his re-election.

The resolution was seconded and supported by several Fellows, and carried unanimously. Mr. Stroud briefly acknowledged the compliment.

**Hon. Secretary.** The PRESIDENT said it afforded him much pleasure to move the re-election of the Hon. Secretary, Mr. MacCormack. The Fellows had only one objection to him, namely, that he moved about so slowly and would not get his injured leg better. (Laughter). He was the kind of man that kept them all up to the scratch. He thought the Society could never have a better Secretary, even if it was possible to have had so good a one. (Hear, hear).

Mr. WILLETT, in seconding the motion, said it was apparent to all the Fellows that the Hon. Secretary was slowly getting better. Personally, he believed that if Mr. MacCormack placed himself under a veterinary surgeon instead of a doctor he would get better much quicker. (Laughter).

The PRESIDENT said that the motion before the meeting was that the Hon. Secretary be re-elected.

Mr. SLOCOCK: On condition that he be fired and blistered! (Laughter).

The motion was then put, and carried with acclamation.

The HON. SECRETARY briefly thanked the Fellows for their further mark of confidence in him.

**Trustees.** The PRESIDENT, in moving the re-election of Messrs. S. H. Slocock, J. Willett, and E. L. Stroud as Trustees, said that the funds seemed to be pretty safe in their hands, and as they had not given any trouble, it was desirable that they should be re-elected.

Mr. JONES seconded the motion, which was carried unanimously.

**Hon. Auditors.** The PRESIDENT said that, according to the Rules, one of the Auditors must be a member of Council, and the other a Fellow of the Society not on the Council. He accordingly moved that the present Auditors, namely, Mr. W. Roger Clarke, representing the Council, and Mr. Eaglesham, representing the remaining Fellows, be re-elected.

Mr. MCINTOSH seconded the motion, which was carried unanimously, and the meeting terminated.

HUGH A. MACCORMACK, Hon. Sec.

According to the annual report of the Salford Veterinary Inspector, during the past year 1137 horses were prepared for human consumption in the public slaughter-houses in the Salford Cattle Market.

## VETERINARY MEDICAL ASSOCIATION OF IRELAND.

A general meeting was held on Friday, May 24th, in the Gresham Hotel, Dublin. Prof. J. J. O'Connor, President, occupied the chair, and the other members present were Messrs. Watson, Cushnahan, Norris, Neary, J. O'Brien, W. W. Malone, Profs. Craig and Browne, Capt. Reavy, Messrs. P. J. Howard, R. H. Lambert, Daly and J. B. Dunlop.

The minutes of the previous meeting, which had been circulated, were taken as read and signed.

The following new members were unanimously elected to membership:—W. J. Doyle, Enniscorthy; E. A. P. White, D.A.T.I.; E. V. Kelly, Oldcastle.

### REPORT OF COUNCIL.

A meeting of Council of the Association was held on the 22nd February, 1918.

A letter from the Victoria Veterinary Benevolent Fund was read, asking for subscriptions. It was resolved that £2 2s. be subscribed this year and that, if the funds permit, a similar subscription be given in future years.

With reference to the grievances of the Veterinary inspectors, it was resolved that some of the Irish M.P.'s be approached with a view to securing their influence in promoting and introducing to the Lords of His Majesty's Treasury the Deputation already appointed by the V.M.A.I., that the following members be appointed to interview the M.P.'s mentioned, and that Mr. O'Connor be interviewed by Mr. Holland; Mr. Devlin by Mr. Cushnahan; Mr. Clancey by Mr. Watson; Sir E. Carson or Capt. Craig by Mr. Johnston; Mr. Redmond by Mr. Howard; Mr. Dillon by Capt. Reavy; and that Mr. McGuinness prepare a statement of the grievances of the veterinary inspectors and send copies of same to each of the said M.P.'s and to each member of the deputation.

A meeting of Council was held on the 22nd March, 1918. Prof. O'Connor was authorised to sign as President of the V.M.A.I., the petition for a Civil List Pension for Mrs. Mettam, sent by the Department of Agriculture per Mr. Howard.

A letter was read from the Master Farriers' Association with reference to increase in the cost of shoeing, etc. It was directed that this letter be acknowledged, and that no action be taken. It was arranged to hold the General Meeting in May, 1918, on a day to be arranged with Mr. Watson, who would read his paper on "Diseases of the cow's udder," prepared for the meeting in last November. Reporter to be engaged as usual.

Mr. WATSON: Since that date I have not received any communication. I was wondering when I would get this information in order that I might approach Mr. Clancey, M.P.

Capt. REAVY: The same thing applies to me. I was speaking to Mr. Dillon and I had not the information to give him.

The CHAIRMAN: I think we have got no information since.

The CHAIRMAN said he would write to Mr. McGuinness and ask him to prepare a statement, and this course it was decided should be adopted.

### DISEASES OF THE COW'S UDDER.

The CHAIRMAN: Our next item is Mr. Watson's paper. At this particular time seeing that so much attention is given to matters of public health, I think Mr. Watson is very happy in the selection of a subject. He has gone into the question of all the principal diseases to be met with in the cow's udder that may be communicated to the human being through the milk supply. I am sure you have all read the paper, and that it can be now taken as read and open for discussion.

Prof. CRAIG : The subject of the paper which Mr. Watson has presented for discussion at this meeting is of very great importance to veterinarians, and especially to those who are interested in Public Health matters. Milk forms an essential portion of the diet of children. It is usually taken in the raw state because many people have a natural prejudice against the use of boiled or pasteurised milk. It is therefore necessary to ensure the wholesome character of this food at its source, and safeguard the public against possible infection from the cow.

If the udder is affected with a disease communicable to man, the milk forms an excellent medium for its conveyance. It therefore behoves us as veterinarians to be in a position to differentiate those diseases of the udder with certainty and in the early stages of their development. Mr. Watson has had more experience than is granted to most of us in the inspection of dairy cows from the public health point of view, and we look to him for light and leading on this important question.

Among the conditions to which he refers in his paper none have received—and deservedly received, so much attention as tuberculosis of the udder. The prevalence of tuberculosis in the cow points to the probability of infection of the human subject with bovine tubercle bacilli, and the recent investigations in connection with the identity of the type of tubercle bacillus in the lesions of tuberculosis in young people prove that milk is one of the actual carriers of the disease from the cow to the human subject. The transmission of tuberculosis by this means not only occurs, but it occurs frequently.

Mr. Watson gives some indication at the end of the paper as to the frequency of tuberculosis of the udder in dairy cows in Dublin, but the evidence is presented with some reservation. If one may take it that the cases noted as "the masses irregular in contour, where no acute inflammation was present" are cases of tuberculosis of the udder, then one may conclude that about 1% of the dairy cows in Dublin have tuberculous udders. Perhaps Mr. Watson can give us some more definite information as to the number of those cases in which tuberculosis of the udder was positively diagnosed. If the percentage I have put down is correct, then it is in accord with that which obtains in many districts in Great Britain.

The infection of the udder by tubercle bacilli has been explained in a variety of ways. It has been thought that backward infection from abdominal lesions through the lymph vessels is the common route, and that the supra-mammary gland is infected before the udder itself. In many cases the evidence on that point is not quite clear. The lesions in the supramammary gland are slight, while those in the udder are extensive and showing numerous caseating and even calcifying centres.

In the diagnosis of the condition considerable difficulty often arises, especially in the case of udders in the early stages of the disease. The affection is difficult to distinguish from other chronic or subacute forms of mastitis; but it would be foolish to treat all cases of chronic mastitis as if the animals were affected with tuberculosis of the udder.

The examination of the milk from the suspected udder is of great value in this connection, and Mr. Watson has dealt with the procedure to be followed in carrying out the examination. But it seems to me that he has not laid sufficient emphasis on the precautions to be taken in the selection of a sample of milk. It is necessary to provide against outside contamination. The milk, say the latter portion of it, must be withdrawn directly from the teat into a sterile bottle. Only then can one be fairly certain that when one finds an acid-fast bacillus in films from the samples that this bacillus is a tubercle bacillus, and is derived from the udder of the cow. If the milk for examination is taken from the common milking pail one cannot but see that a serious source of

error may arise in diagnosis. I do not know if that happened in the case of the red cow which he mentioned as one of the cases which caused him trouble. Where the microscopic examination is negative one can not conclude that the udder is free from tuberculosis. One can only state that one has been unable to find tubercle bacilli in the sample of milk. Sometimes, however, obvious infection of a different nature is observed on microscopic examination. But where this is not noted, biological experiment is a useful procedure for the purpose of diagnosis. It has, however, the defect that one has to wait several weeks for the result.

In the meantime the application of the tuberculin test is of some service here—in this way. A positive reaction gives no indication of the position of the tubercular lesions in the body, but a want of reaction in an otherwise apparently healthy animal points to the absence of tuberculosis.

As Mr. Watson has noted, it has been shown that tubercle bacilli may find their way into the milk from udders which are apparently healthy. This has been noted in some cows showing clinical symptoms of tuberculosis and the infection of the milk has been proved, but only by biological experiment.

It is also interesting to remember that tubercle bacilli have been excreted for a long time in the milk of cows which in their earlier days were immunized with vaccines prepared from human tubercle bacilli.

Mr. Watson refers to the use of cultures for the purpose of diagnosis. Cultivation of tubercle bacilli from milk in the cases where it might be useful is not practicable, because of the scarcity of the organisms and the very slow growth of the tubercle bacillus in culture.

Regarding actinomycosis of the udder, the essayist remarks that he feels certain it is of rare occurrence. That is of some interest. In Lanarkshire some fifty udders showing lesions suspicious of tuberculosis were examined, and of these five proved to be cases of actinomycosis. Possibly actinomycosis of the udder is more frequent in some districts than in others.

The only other condition to which I would refer is botryomycosis, I would like to ask Mr. Watson if he has ever come across any example of that disease in the cow.

In the prevention of tuberculosis in man the Tuberculosis Orders which were introduced before the war, but which are now in abeyance, would have gone far to safeguard the public health against tubercular infection from a bovine source. No doubt the time will come, and probably at no far distant date, when the veterinary inspector will be called upon again to carry out his onerous duties in connection with the Tuberculosis Orders of 1913 and 1914. It is therefore not inopportune for us to discuss such a paper as Mr. Watson has brought forward, and I think he deserves our very best thanks for preparing and presenting the paper for discussion at this meeting of the Association.

Capt. REAVY : I have not had the pleasure of reading this paper all through, but I have nothing to say but praise of it. I agree with all that Prof. Craig has said. It is very important that veterinary surgeons should know everything with reference to milk supply. The question I would ask is why was the Tuberculosis Order put in abeyance, and by whom? I think at the present time, when we are led to believe that milk is a great source of tuberculosis when transmitted to children especially, and now that the aim and interest of every one is to preserve the manhood of the country, it is a pertinent question to ask why this Order was put in abeyance?

Mr. NORRIS : I agree with the previous speakers that we have no more able exponent of the subject than Mr. Watson, who has had a long experience of udder disease in the abattoir and dairy yard. Anything I have to say will not be in the nature of criticism, but rather to

emphasize some of the more important points made in the paper. As Capt. Reavy has said, the public has a vague idea that young children are sometimes liable to tubercular infection from drinking cows' milk. The latest statistics of competent research workers show that almost 80 % of the cases of fatal tuberculosis investigated in children under 5 years of age are due to bacilli of bovine strain. In adult life the percentage of cases of bovine origin dwindles considerably. As a rule in the cases in children the lesions were found to be abdominal, pointing to the probability of milk being the vehicle of infection. We could ask for no stronger evidence to magnify the importance of udder tuberculosis than the result of these researches.

As to the diagnosis of mammary tuberculosis, I agree with Mr. Watson that the history of the case, the development of the lesion, and the clinical appearances are very important aids; but, of course, one should not stop at the clinical examination. It is necessary to reveal the tubercle bacillus before giving a definite opinion. Microscopic examination in this respect is not altogether reliable, and a negative result should always be considered in conjunction with the history of the case before a final decision is given. Cultures are perhaps the least satisfactory method of diagnosis; not because of the difficulty of obtaining pure seed material, but owing to the slow growing habit of the bovine type. Undoubtedly the most satisfactory method is guinea-pig inoculation.

A point that I would like to emphasise is that primary infection of the udder is rare. We almost always find tuberculosis of the peritoneum in association with the udder lesions. How the disease spreads from the former to the latter is perhaps a debatable point, although *via* the lymphatics is generally accepted.

The only thing I have to complain of in the paper is that although Mr. Watson has dealt with the subject fully he does not give a hint as to what are the proper steps to secure a tubercle-free milk supply to the community—a point which occupied the minds of many engaged in agriculture and public health questions before the war. Toward the end of his paper Mr. Watson states: "The system that exists in my bailiwick is," etc. If the statement is an accurate description of the case as it applies to this city, I think it is most unsatisfactory. It is more or less useless to hand over a sample of milk to a medical man, who, perhaps, knows nothing about the case, to make a microscopic examination of a slide or two, and if the result is negative to allow the matter to drop. I think, and I am sure all here will agree with me, that the examination, both clinical and bacteriological, should be in the hands of the veterinary officer from beginning to end.

Prof. BROWNE: I have very few remarks to make on this subject. Mr. Watson has given us some of his personal experiences on the subject, and I think it is a great pity that he did not give us some more of them, because he is exceptionally fitted to do so, and his experience extends over—I won't say how many years. There is one branch of the subject on which I have some little experience, and that is examination of milk for tubercle bacilli. During all the years when I was an assistant with Prof. Mettam I examined quite a number of specimens of milk. At that time the Tuberculosis Order was in operation, and I can assure you that it was only in a very small number of cases that he was able to find any tubercle bacilli.

Mr. D. NEARY: As far as tuberculosis is concerned, the ordinary country practitioner has very little chance of knowing. Personally, as far as my experience goes, I think the percentage of tuberculous cattle must be very small.

(To be concluded).

# PARLIAMENTARY.

In the House of Commons, Tuesday, Oct. 22nd.

## OUTBREAK OF RABIES.

Mr. PROTHERO, replying to Sir W. Bull (Hammer-smith, U.), who asked whether he was aware that a British officer flew over from France with a lady's dog which, it was alleged, spread rabies in Devon; and, if so, what punishment would be meted out to the officer for evading the law, said:—The Board have no knowledge of the circumstance to which my hon. friend refers, and if he will send me his information, I will have it investigated. In January and February, 1917, the Board called attention to this possible source of risk, and both the Admiralty and the Royal Flying Corps gave every assistance by warning officers of the serious breach of regulations involved. I may, perhaps, take this opportunity of explaining the gravity of the present position. In all, 40 cases of rabies have been confirmed since Sept. 7—35 in Devon and 5 in Cornwall: of these no fewer than 29 occurred in the County Borough of Plymouth. But these figures do not by any means represent all the facts of the case. I am satisfied that rabies has been in existence in these counties for several months, probably since the end of May, and the latest outbreak discovered is in the Wadebridge district of Cornwall, some 30 miles distant from Plymouth. Here the rabid dog was owned by an hotelkeeper, and enquiries have shown that another of her dogs had died of rabies three weeks ago, whilst other very suspicious deaths of dogs are now known to have occurred in the immediate neighbourhood during the month of September. Visitors with dogs had been staying at this hotel, and as many as seven dogs which are known to have been in daily contact with the hotelkeeper's dogs during this summer have been taken to places outside Devon and Cornwall. These have now all been traced and isolated. It will be seen that grave risk of the spread of this disease to other parts of the country has thus been incurred, and I desire to make a strong appeal to all persons who have visited Devon or Cornwall with dogs during the last five months that they should place their dogs with veterinary surgeons at once and inform my Department of the fact. I regret to say that the appeal for this information issued to the Press on the 11th inst. has only met with one response. Human life is at stake in this matter. (Hear, hear). At least 21 persons are known to have been bitten by these rabid dogs, nine being children, and any person who fails to assist by giving the information required will incur a very grave responsibility, should the disease spread to other districts. I would like also to appeal to the manufacturers of wire muzzles to come to my aid by greatly and rapidly increasing their output. The deficiencies of supply hinder the measures necessary for stamping out this disease.

Sir W. BULL: Has not a barrister of standing communicated the name of the officer, the date of the occurrence, and the name of the dog? Mr. Prothero: Not to my knowledge. The information has not been communicated to me, or, at least, in such a way that it reached me. Mr. Lambert (Devon, S. Molton): How did this outbreak in Devon and Cornwall first occur? Mr. Prothero: That is just the difficulty. I can't explain it. I may have a suspicion, but I should not like to say on suspicion what I believe the cause to be. It will be observed the danger is mainly centred in the County Borough of Plymouth. Mr. Chancellor (Haggerston, L.): Has death resulted from any of these bites from rabid dogs? Mr. Prothero: Not at present.

## V.V.B. FUND.—CORRECTION.

In the list of donations at p. 130, of last week's issue, for J. Holland, read, J. HAMMOND £100.

## REVIEW.

**MASTITIS OF THE COW.** By SVEN WALL, Assistant in the Veterinary High School at Stockholm. Authorised translation with Annotations by Dr. Walter J. Crocker, B.S., V.M.D., Professor of Veterinary Pathology, University of Pennsylvania. Pp. xj + 166, with 23 illustrations. Price 12/6 net. (J. B. Lippincott Company, Philadelphia and 16 John Street, Adelphi, W.C., 2, London.)

Prof. Crocker has earned the gratitude of English-speaking veterinarians by placing this edition of Sven Wall's well-known work within their reach. We know no book which treats the subject so completely; and its publication fills a gap in our literature. As the work will be new to nearly all English readers, it is well to summarise its arrangement and contents.

After an initial chapter giving a concise and adequate anatomical survey of the bovine udder, four chapters deal with mastitis in general, its various causes, and the types of infection. These lead up to the following seven chapters, in which the various types of udder-infection, common and rare, are considered in detail. Streptomycosis, staphylococcosis, colibacillosis, pyobacillosis, tuberculosis, actinomycosis, and necrobacillosis of the udder each receive a separate chapter and are fully and carefully described. This includes a consideration of their prognosis and treatment. Then follow two chapters dealing respectively with the clinical and post-mortem diagnosis of mastitis, which will give valuable assistance in the differentiation between the various forms, when that is possible. These nine chapters form the kernel of the work, the remaining four chapters being mainly summarising and illustrative. These latter comprise short but sufficient chapters upon the importance of mastitis in milk control and meat inspection, the first containing some useful statistics; a longer one of post-mortem reports upon some sixteen cases of single and mixed udder-infections; and a concluding one of clinical reports of a few cases of contagious udder-infections checked by bacteriological examinations of milk samples.

As usual in such works, a minute examination detects points more or less open to criticism. The recommendation on page 50, to give camphor as a febrifuge in streptococcal mastitis in doses of five grains daily, must surely be a mistake for grammes; and it is not certain that the author is right in stating positively, as he seems to do on page 87, that the tubercle bacillus does not form spores. On page 49 the heading of "Typical Chronic Streptomycosis" appears to have been inadvertently omitted, with resultant confusion of that condition with the preceding one of Atypical chronic streptomycosis. Some of the therapeutic teaching, also, such as the frequently advised use of the actual cautery, may not be acceptable to many English readers. On the whole, however, the book must be pronounced a very valuable one to country practitioners. Few, perhaps, have sufficiently thought out the pathological processes underlying the various forms of mastitis; and the work gives all details of this nature with quite sufficient fullness for the purposes of the clinician. Some, again, trouble little about differentiating between the non-tubercular forms of mastitis; and as regards this question, which is by no means without practical importance, the book gives valuable information. It is a well-written summary of the clinical and experimental observations of an acknowledged authority on mastitis; and the majority of clinicians, after reading it carefully, will find their ideas of the subject much more accurate and systematic than before. It may fairly be said that every veterinarian who is concerned with bovine disease at all will do well to add it to his library.

The tabular summaries which generally terminate the chapters might be omitted from future editions without disadvantage, as it is difficult to see any real utility in them.

W.R.C.

## The A.V.C. Comforts Fund.

To the Editor of "The Veterinary Record."

Dear Sir,—Will you, on behalf of the Committee, Army Veterinary Corps Comforts Fund, very kindly insert in *The Record* the enclosed lists of subscriptions and gifts which have already, most generously, been given to the Fund for the winter of 1918-19.

The Committee is very grateful and would like to thank all those who have already given such substantial help, they will also gladly receive any woollen or other gifts which should be sent in as soon as possible in order that they may be despatched before the intense cold sets in.

Subscriptions are most welcome at all times.

Yours faithfully,

E. A. BLENKINSOP.

## ARMY VETERINARY SERVICE

War Office, Oct. 15.

The King has been pleased to approve of the following  
 awards to the following Officers and Warrant Officers in  
 recognition of their gallantry and devotion to duty in  
 the field:—

## THE MILITARY CROSS.

\* \* \* \*

Temp. Capt. THOMAS WALSH McMAHON, A.V.C.—For  
 conspicuous gallantry and devotion to duty. He ad-  
 vanced with the brigade and established his collecting  
 posts, dressing and evacuating wounded horses under  
 intense machine-gun fire, in addition to shell fire and  
 bombing from enemy aeroplanes. By his fine example  
 and encouragement to his men he was enabled to dress  
 and evacuate some 250 horses which would otherwise  
 have been lost.

Buckingham Palace, Oct. 19.

The King held an Investiture this morning at 10.30  
 o'clock.

The following Officers were severally introduced into  
 the presence of His Majesty, when the King invested  
 them with the Insignia of the respective Divisions of  
 the Orders to which they have been admitted:—

## THE DISTINGUISHED SERVICE ORDER.

\* \* \* \*

Major GREATLY SAUNDERS, Canadian A.V.C.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Oct. 17.

REGULAR FORCES. ARMY VETERINARY CORPS.

To be temp. Hon. Lt.:—M. Foster (Oct. 17).

Oct. 19.  
Lt.-Col. W. D. Smith, c.m.g., d.s.o., relinquishes the temp. rank of Brig.-Gen. on ceasing to hold the appt. of Dir. of Vety. Servs. (Sept. 25).

Lt.-Col. W. D. Smith, c.m.g., d.s.o., to be actg. Col. while holding the appt. of Dep. Dir. of Vety. Servs. (Sept. 28).

Oct. 21.  
To be actg. Lt.-Cols. whilst holding the appt. of Asst. Dir. of Vety. Servs.:—Maj. F. Fail, Maj. J. Nicholas (July 1); Maj. W. A. Jelbart, Temp. Capt. D. O. Turnbull, d.s.o. (Sept. 1).

Cpts. to be actg. Majs. whilst holding the appt. of Dep. Asst. Dir. of Vety. Servs.:—A. A. Pryer, d.s.o. (Aug. 21); J. G. McGregor (T.F.) (Sept. 1).

Temp. Qrmr. and Hon. Lieut. H. J. Arnold resigns his commn. (Oct. 22).

Temp. Qrmr. and Lt. G. F. Galloway to be Capt. under Art. 330, R. Wt. for pay and promotion (Oct. 10).

Oct. 22.  
To be temp. Lieut.:—R. B. Catt (Aug. 16).

Oct. 24.  
Asst. Dir. of Vety. Servs. and Remnts. (Class X).—Temp. Capt. (temp. Maj.) A. G. Doherty, m.c. (Capt. E. Afr. Vety. Dept.) from Dep. Asst. Dir. of Remnts. (Cl. BB) and to be temp. Lt.-Col. whilst so empld. (July 5).

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1582

NOVEMBER 2, 1918.

VOL. XXXI.

## "CASTING SHADOWS BEFORE."

The present condition of affairs on the Continent renders several prospective measures of more urgent importance, and foreshadows new work for the Council. The recommendations for financial assistance to veterinary students is one such question which was dealt with at the last Council meeting, and suggestions for a scheme for the purpose were decided upon there and then. The Government Departments entrusted with these various measures desire to have their schemes drawn up and in order; and the Council did well to act quickly.

Another subject upon which communications have already passed between the Council and the Government, is the re-settlement of veterinary surgeons in civil life after the war. If the Government takes any steps at all it will need veterinary advice; and evidently that necessity is recognised. Much in the history of the last four years, including the recent creation of the Veterinary Tribunal, shows that Government Departments now recognise our Council as representing the profession; and we may be sure that the Council will receive a hearing when any other veterinary body would be disregarded.

## THE COLLEGE FINANCES.

Last week—the last Saturday in October—the published total of voluntary subscriptions was £1074 4s. 11d. These figures show substantial improvement upon 1917, when the total for the whole year was only £960. Considering that September is a holiday month, the increment of rather over £100 in the two months may be considered fair progress. Two more months of 1918 still remain to us, and we may reasonably hope to see the pace accelerated, and considerable addition made to what is already a respectable total.

We should remember the Treasurer's words at last Council meeting—"Our expenses may be counted at somewhere about £1500 a year," and he proceeded to urge those members who had not yet subscribed to do so. This shows that though we are doing better this year than ever before, we have not yet done enough.

## UDDER TROUBLE IN COWS.

In the reports of two Societies which appear in our pages this week there is much said on Tuberculosis of the udder, and on Septic mammitis. In the former, difficulty in diagnosis is a marked feature. In the latter unsatisfactory methods of treatment are emphasized. The author of the paper gives a prophylactic treatment which has proved successful in his hands; but as the disease is largely seasonal, little use is likely to be made of it at pre-

sent. In both conditions there is danger in the milk, and a loss to cattle owners which in the aggregate must be very considerable.

In the course of a discussion it was stated that the Tuberculosis Order 1914 was "hung up" for want of money. But was it not for lack of men—at any rate on this side St. George's Channel?

## BACTERIAL ASSOCIATIONS IN EPIZOOTIC LYMPHANGITIS.

M. Carpano published the result of some researches upon this subject in the *Annali d'Igiene* of this year. He subjected numerous samples of the purulent exudate of epizootic lymphangitis to systematic bacteriological examination, and found that Rivolta's cryptococcus is very often accompanied by streptococci and staphylococci, even when the material examined has been obtained from deep and previously unopened lesions.

Carpano ascertained the presence of these germs by using a special culture medium, with which he tested 41 samples. In these 41 samples he found streptococci 25 times (= 59 p.c.) and staphylococci 17 times (= 41 p.c.). In 14 samples Rivolta's cryptococcus was found alone; in 15 it was associated with both streptococci and staphylococci; in 10 it was associated with only streptococci; and in 2 with only staphylococci.

After a detailed morphological, cultural, and biological study of these associated germs, Carpano places them as streptococci of the *adenitis equi* type and as *Staphylococcus pyogenes* in its different varieties; both remarkable for their prominent pathogenic properties.

Carpano then asks, What is the influence of these microbes upon the origin, the clinical picture, the course, and the result of epizootic lymphangitis? Undoubtedly, he thinks, the concomitant action of these germs cannot be negligible, in view of the high sensibility of horses to pyogenic microbes. If such agents with their various toxic products are capable when alone of causing important general and local disturbances, it is not an exaggeration to admit that the gravity of epizootic lymphangitis may be very largely attributable to association with these microbes. This is similar to what occurs when pyogenic organisms are present in such diseases as pneumonia, glanders, tuberculosis, actinomycosis, etc.

In conclusion, Carpano justly calls attention to the necessity of taking these bacterial associations into consideration in experiments upon the immunisation against and therapy of epizootic lymphangitis. - (*La Clinica Veterinaria*).

# VETERINARY MEDICAL ASSOCIATION OF IRELAND.

(Concluded from p. 140).

Mr. CUSHNAHAN: Mr. Watson has been very happy in his selection of a paper, and I am sure no one is in a better position to speak on this subject than he is. I have been with him on some of this work and the cases I saw were both interesting and important. Regarding the diagnosis of tuberculosis of the udder, we are told that the part does not show any inflammation: that one quarter only, generally the posterior, is affected, and that it has a cold feel. I have seen cases where the condition presents the appearance of a subacute mastitis. On one occasion I had an opportunity of seeing in the abattoir, with Mr. Watson, a cow which looked apparently healthy. Her udder did not suggest that she was affected with tuberculosis; one quarter was slightly enlarged, with a considerable amount of heat—what might be termed a subacute inflammation. In this particular case credit is due to Mr. Dolan, Mr. Watson's assistant. A specimen of milk was sent to a well-known bacteriologist, a medical man in this city, for examination. He failed to find tubercle bacilli. Mr. Dolan, however, was not satisfied, and he also examined the milk microscopically and found acid-fast bacilli. The cow was slaughtered. I was present at the post-mortem examination, the viscera appeared normal, tubercular lesions were absent on pleura and peritoneum, but when the lungs were cut into they were found to be practically a mucous mass. One quarter of the udder was decidedly tuberculous, the supra-mammary gland was enlarged, but we could not find any definite tubercular lesions in it. The post-mortem confirmed the diagnosis, viz., that the case was one of tuberculosis of the udder. In this connection mention has been made of the milk ducts—the ducts of the teat—as channels of infection. I think it is more likely that infection takes place through the blood stream, and this particular case mentioned would, I think, go to prove that.

Mr. Watson mentioned cases of chronic induration of udder, and also purulent affections, and the difficulty in arriving at a diagnosis. In these cases the milk should be examined microscopically, and if with negative results, the animal should be submitted to the tuberculin test. If she reacts she should at once be put aside as tuberculous. If, however, she fails to react and is yielding purulent milk, she should be considered as a menace to the public health and put aside also. I have seen milk teeming with streptococci and I have no doubt that milk of this description causes many illnesses in children, at least. In medical circles I think it is an accepted fact that a large percentage of cases of tubercle in children are of bovine origin. In Edinburgh it has been shown that of the cases of tuberculosis in children the percentage due to bovine origin is very high. In New York the deaths amongst children are from six to ten per cent., while bone cases are as high as 70 per cent., according to Smith. It has been pointed out by Griffith that in children under ten years nearly 75 per cent. of the cervical gland cases are of bovine origin. I should say a large percentage of mesenteric and intestinal lesions of tuberculosis in children must be due to the bovine type of bacillus. From what we know of the transmission of bovine tuberculosis to human beings it seems strange that so much money is spent in trying to eradicate the disease in man without simultaneous action being taken in regard to cattle. Notwithstanding the war, I do not think the Tuberculosis Order should have been suspended.

Prof. CRAIG mentions a very important matter in the examination of milk, namely, to have vessels and bottles in which samples are taken sterilised beforehand. It is

also important to have the milk from the suspected cow taken separately, and from the affected quarter, if any one quarter of the udder is affected.

On the subject of actinomycosis, I remember some years ago reading a report of the Medical Officer of Health for Lanark, and it was surprising the number of cases of actino. of the udder he found. I presume his cases were confined to biological examination? It seems strange that fewer cases of actino. of the udder should be found elsewhere than in Lanark. I think that generally most veterinarians are satisfied with the clinical examination. In my opinion they should, as often as the opportunity presents itself, have recourse to the biological test.

Mr. Watson has mentioned in his paper malignant tumours of the udder. Seeing that the origin of these is still obscure, an animal whose udder is affected with such should not be used for milking purposes.

Foot-and-mouth disease is one of the diseases mentioned as being communicable to human beings. The risk of its transmission is regarded lightly by some. I should mention a case where a doctor in a certain district where foot-and-mouth disease existed, mentioned to me a case of a child affected with an aphthous condition which he had difficulty in diagnosing. Foot-and-mouth disease existed on the farm where the child was reared, and it was drinking cows' milk. He told me that he could arrive at no other conclusion than that the case was one of foot-and-mouth infection. He was a very tactful and diplomatic practitioner: he kept his opinion to himself lest a scare might be made in the district.

Of the diseases communicable to man through milk—that is, from a diseased udder—I do not mean those diseases where milk is only a medium for conveying micro-organisms, there is the greatest risk from tuberculosis, and as too much care cannot be used in diagnosing this or any other diseased condition of the udder, I quite agree with Mr. Norris—that the medical officer should not usurp the work and duties of the veterinarian. The veterinary surgeon is qualified, or I should say the only person qualified, to do both the clinical and bacteriological part of the work, and I don't see why a medical man should step in and say whether any particular case is tuberculosis or is not. Many mistakes are made in this way, and in the interest of the public health it is time something should be done to prevent them.

Mr. Norris appeared to be disappointed that mention was not made in the paper regarding the subject of tubercle-free herds. Now, I think that this is a matter worthy of a paper in itself. Perhaps at a future meeting of this Association some member will be good enough to bring the subject forward for discussion.

I have much pleasure in congratulating Mr. Watson on his able paper.

Mr. DUNLOP: I have read Mr. Watson's paper with pleasure and profit. Mr. Watson has dealt with the subject of diseases of the cow's udder in a thorough and practical manner. I do not think we can find fault with the paper except that it was too short. It is to be hoped that he will remedy the defect in the near future.

Mr. Watson says, "milk is the beverage of the poor and the rich." Bang, and other distinguished authorities hold that it is quite possible to have tubercle bacilli in the milk without any tubercular lesions being present in the mammary gland. Other leading bacteriologists, as Principal Mettam, B.Sc., aver that you cannot have tubercle bacilli in the milk without a tubercular lesion in the gland. The latter say, it is not because the lesion cannot be found that it must necessarily be absent." There is practically no difference of opinion here. It therefore follows that if we

are to have a pure milk supply we must have all reactors removed from the dairy. What then is to be done with reactors? Are they to be destroyed? That would make meat scarce and dear. The country could not afford the money for compensation. The health of the community, especially of the poor, would suffer.

It has been proposed in Scotland recently that the carcasses of all reactors, or at any rate diseased animals, should be cooked under steam pressure in such a way as to thoroughly sterilise the meat to the centre. Some people do not relish this idea. A better course to adopt, I think, would be to brand all reactors on the hoof and, after killing, give the carcasses an *extra-special* careful inspection. With a view to economy, reactors should be prepared for the butcher. At present, reactors and disease-proof cattle are killed promiscuously, and many animals are not inspected at all. Visibly affected animals should be handed over to the knacker, and in the interests of public health the owner should be compensated for any carcass or part of a carcass condemned.

The inmates of Peamount Sanatorium are supplied with milk free from tubercle bacilli. The Department of Agriculture send into Dublin a quantity of pure milk, but for a city like Dublin, this is only a drop in the bucket. The question naturally arises, What becomes of the reactors removed from the dairy? Have they been sold in the market to find their way into other dairies, to further deteriorate and to further contaminate other already infected herds.

A number of years ago Lady Aberdeen received from America a complete plant for pasteurising milk, which she kindly handed over to the Dublin Corporation. Prof. McWeeny, addressing a meeting in the Mansion House during the Baby Week, said that pasteurisation did not destroy the tubercle bacilli; and he is supported in that opinion by other eminent authorities. He said the milk should be boiled, I think he said for a few seconds, and then allowed to cool slowly.

The Liverpool Corporation supply sterilized milk, but in some cases it has induced in infants a form of scurvy, easily recognised by Liverpool specialists. Some medical men recommend bringing the milk to the boiling point and letting it cool gradually, and they use simple means to prevent scurvy in the infants.

The Glasgow Corporation recommend natural milk, and take measures to have the milk supply as clean and pure as possible.

The Melbourne Corporation have abandoned sterilising milk, and with good results have gone in for a pure supply.

Sir John McFadyean said tuberculosis is a purely infectious disease. Few will gainsay that statement. Every infectious disease is purely infectious. If there were no specific infection we would not have the specific disease. He argues that because no baby or calf is (with rare exceptions) born with tuberculosis, the disease is not hereditary. How could the born or the unborn contract an infectious disease if the specific bacillus did not come into contact with the body? It so happens that the foetal membranes are a most efficient barrier or filter to the passing of the tubercle bacillus. There is something in the tissues and lymph of the foetal membranes which is antagonistic to the specific microbe, and to some other microbes as well. This something exists in a varying degree in all our bodies, or we would be all dead men. It is this, a something which is not only hereditary but congenital as well. It is no argument to say that because this which we all inherit more or less can be increased or diminished according to our mode of living that the predisposition to disease is not hereditary. We all admit the importance of disinfection and sanitation. In all infectious diseases a great deal depends on the dose and the frequency of the dose.

The simple and sure method of banishing from our shores the disease in cattle is to breed from healthy cattle only (preferably not too young) that have been known to resist the disease. If we cannot do this properly then the Department ought to do it for us. No bull should be kept for stock purposes that has not been carefully tested. Like tends to beget like. It is a shame for us to allow the foreigner to select and carry off the healthiest of our cattle for stock purposes.

The Royal Dublin Society, the pioneer society in the promotion of Agriculture, Science and Art, has taken a step in the right direction. Before the outbreak of the war it passed a bye-law that dairy cows must pass the tuberculin test before being exhibited.

The CHAIRMAN said he wished to congratulate Mr. Watson on bringing forward a paper of great practical importance from the point of view of the veterinarian and that of public health.

The important points dealt with in the paper have been fully discussed by the various speakers, most of whom, like the essayist, have had extensive experience in the examination of cows' udders in dead or living subjects.

Mr. Watson's reputation and great opportunities for studying the several affections of the udder of the cow led us to expect, perhaps, more information from his treatise than it would be possible to give. He has given a lucid exposition of our present knowledge on the affections of the mammary gland which may render the milk secreted by it dangerous for ingestion by the human being. Tuberculosis overshadows in gravity all the other lesions of the organ. Judging from the records of cases of human consumption resulting from drinking milk from tuberculous udders, the danger of the latter to the public health is appalling, and taking into account the admitted difficulty in many cases of diagnosing tuberculosis of the mammary gland it would seem as if the only reliable method of safeguarding the human subject from this source of the scourge would be to insist on all dairy cows passing the tuberculin test, especially when one remembers how easy it is for the milk to become contaminated from open lesions in other parts of the body. The next best procedure would be to assume that all chronic enlargements of the mammary gland are of tubercular origin, and not depend upon mere microscopic examination of the milk to confirm the diagnosis; and to condemn all subjects clinically affected in other parts of the system.

Mr. Dunlop introduced a good point in advocating the eventual establishment of tubercle-free herds by breeding only from stock which are not the progeny of animals affected with the disease, on the ground that there is a hereditary predisposition to the latter. There is no doubt that some subjects are more susceptible to tuberculosis than others, and I think it is reasonable to believe that this susceptibility is hereditary, as seems proved in the case of the human subject. I was surprised to learn from Mr. Watson's paper that he, as Borough Veterinary Officer, has not entire control of the diagnosis of tuberculosis of the udder in the dairy cows of the city, and I agree with Mr. Norris that the arrangement whereby a medical man has the final say in a case of doubtful diagnosis is obviously most unsatisfactory.

It does seem blind policy on the part of the Government, as Capt. Reavy points out, that in a critical time like the present, when the conservation of the manhood of the country is of such vital importance, the Tuberculosis Order should be suspended. The cost of administering the Order would be insignificant compared with the saving of valuable human lives entailed by its being enforced. I have great pleasure in congratulating Mr. Watson on his very able paper.

## REPLY.

Mr. WATSON: I have to thank you sincerely for the mild, kind, and generous way in which you treated this paper. The question of the milk from a public health aspect has received very great attention from the gentlemen of the fourth estate lately on account of Professor Henston's attack on the Dublin milk supply. I think it was Dr. Oliver St. Gogarty who said that the milk of Dublin was so absolutely swarming with germs that it would be preferable to take a drink of the Liffey in its worst condition. However, we don't mind being ragged in Dublin, particularly the officials. Prof. Craig and a number of other speakers wished to get some more definite methods of diagnosing tuberculosis of the udder. I remember being at a meeting of the Association of Veterinary Officers of Health, held some years ago in London, and there was among those present a very distinguished Manchester Veterinary Inspector, Mr. Brittlebank, who asked, like a prophet in the wilderness, "Was there anyone who could give him a tip as to how to definitely diagnose tuberculosis?" I thoroughly agree with Prof. Craig when he draws your special attention to the greater importance of milk, from a public health point of view, in conveying disease from animal to man, for after all, as the Professor says, we use our milk raw. Prof. Craig took me to book for the figures given at the end of the paper, and he wanted something more definite. I may say I am not in a position to give him anything more definite. During all the years for which I give these figures there was a difficulty in getting the Committee to sanction the slaughter of animals; they are always thinking about their own pockets, and they are very particular about the rules of the City, and particularly where they think they are doing a good turn to a dairyman. Unless you have the power of absolutely slaughtering the animal on your certificate you cannot follow it up and make post-mortem examination. Prof. Craig spoke about examining the supramammary lymphatic glands. I have tried it hundreds of times, and it is almost impossible even when it is enlarged.

Prof. CRAIG: I meant after death.

Mr. WATSON: I have tried it in life. There was a question of the mammary glands becoming infected with tuberculosis. Prof. Craig preached the doctrine that it came from the peritoneum; but I tell him I cannot support that, because in the post-mortem examination, and that is more important, I have seen tuberculosis of the udder. I have arrived at only one form of infection of the udder by tuberculosis, and that is by the blood-stream. As to the public health aspect of using the blood of the tuberculous animal for edible purposes, someone interested in that question recently, before the Public Health Committee, made an order that the blood of tuberculous animals was not to be used. We sold some of the blood of the animals slaughtered in the abattoir for making black-puddings, but the Committee held that there might be a source of infection, forgetting altogether that even black-puddings are cooked. It is quite easy to destroy all the blood by selling it for manure. I cannot subscribe to the doctrine that because an animal is tuberculous, that tuberculosis is in the blood-stream. The only cases in which you find the bacilli in the blood-stream is in miliary tuberculosis. Talking about the difficulties of diagnosing tuberculosis of the udder, I remember a case where I absolutely felt inclined to put my last shilling that I was up against a case of tuberculosis, and after the most searching examination it turned out to be staphylococcus. There is no method of dealing with tuberculosis of the udder, and I don't think any man has ever described the physical symptoms. It must be by biological and microscopical tests.

Capt. Reavy wants to know why the Tuberculosis Order was hung up. It was hung up for the good old

excuse—want of money. Prof. Norris gave some important statistics about the number of children who had tuberculosis of the tonsils and of the mesenteric lymphatics. I remember reading the statement of a German professor, who said that in every instance where he made a post-mortem on children he found tubercle bacilli in all the mesenteric lymphatics, and he arrived at the conclusion that you could not find any children who had not. As regards the primary infection, really I have expressed my opinion on that. I can never believe that the infection can be through the teat.

[Prof. NORRIS: As far as I can see now there is no acceptable solution for that infection where you have infection of the udder and no infection in the abdominal cavity except the teat.]

In reference to Mr. Norris' remarks as to the Medical Officer of Health, I am sorry my words conveyed an erroneous impression, as they were meant to refer to the time antecedent to the passing of the Tuberculosis Prevention (Ireland) Act of 1908. Since then my certificate has always been accepted by the Public Health Committee. I am confident you will all agree that the veterinary profession has no more stalwart champion than the General Medical Officer of Health of Dublin—Sir Charles Cameron.

In conclusion, I may say that I am extremely thankful for the generous way in which you received my efforts. (Applause).

On the proposition of Capt. Reavy, seconded by Prof. Craig, a vote of thanks was passed to Mr. Watson for his paper, and the proceedings concluded.

## NORTH OF SCOTLAND VETERINARY SOCIETY.

[NATIONAL V.M.A.—SCOTTISH BRANCH.]

The half-yearly meeting was held in the Agricultural Department, Marischal College, Aberdeen, on Aug. 29, Mr. William Brown, President, in the chair.

There were present: Messrs. Anderson, Keith; Beattie, Longside; Cumming, Peterculter; Clerk, Stonehaven; Drennan, and Hepburn, Aberdeen; Howie, Alford; Johnston, Auchterless; Kerr, Ellon; Murray, Cullen; McPherson, Huntly; McFarlane, Aberchirder. Apologies for inability to be present were received from Messrs. Niven, Sievwright and Crabb.

The minutes of the last meeting, as they appeared in *The Veterinary Record*, were taken as read.

## PECULIAR CASE OF EMACIATION IN A HORSE.

By R. E. DRENNAN, M.R.C.V.S., Aberdeen.

*Subject.* A Bay Clydesdale gelding, ten years old, belonging to one of the principal coal merchants in the city, where he had been working regularly for five years. The hygienic and feeding arrangements in the stable were perfect. I was called in to see the animal in the beginning of March, this year.

*History.* The animal, though feeding quite well and working regularly, seemed to be falling away gradually in condition. For a week or two the stableman, who is a very careful man, was under the impression that his teeth perhaps wanted attention, so I had them examined and carefully dressed. I also made a careful examination of the animal, but could find nothing of any importance about him; pulse and temperature quite normal, taking his food quite well, and to all external appearances, apart from his poor condition, the horse seemed quite well. I suggested that I might try him with a few tonic powders in his food, and left instructions with the stableman to see that he was not overworked, and to feed him carefully and well. The powders consisted chiefly of calcium phosphate and sulphate

of iron. On my second visit, a week later, I found him in practically the same condition. I continued the powders for a week or two with some vermifuge medicine added, suspecting that there might be worms about the stomach or bowels. On my third visit, about a fortnight from my first, he seemed to be gradually getting poorer instead of improving, and was becoming indifferent to food. The pulse, if anything, was faster and weaker, and temperature was 103° F. I informed the manager about the condition and advised that the animal be placed in a comfortable loose-box and be taken off work, as I suspected something seriously wrong with him. When his temperature began to rise I examined the chest thoroughly, but could find no abnormal sounds, the breathing being quite normal.

A day or two later he began to show signs of some little difficulty in breathing. The lower parts of the lungs were a bit dull; membranes very bilious looking and somewhat congested, pulse 70, and temperature 105°. I applied a stimulating liniment to chest, and had him well clothed with rugs. A day or two afterwards the temperature came down to 103, but by this time signs of colicky pains were shown after eating the slightest quantity of food. After a fortnight or so in the loose-box the manager asked my opinion of the case. I informed him that the animal was suffering from a very bad form of liver trouble—probably an enlarged liver—from the dullness on palpation in that region; or an abscess, either attached to or in the region of the liver, interfering with the digestive organs, and probably through pressure on the stomach causing the slight colicky pains after feeding. I gave very little hope of his recovery.

The animal got gradually more emaciated; temperature rising and falling every alternate day; pulse very fast and weak; mucous membranes very bilious and congested; until the end of two months from the time the stableman first took notice of him he was so thin and weak that he was scarcely able to stand, and when he got down there was difficulty in getting him up again. I gave up all hopes of his recovery and advised that he should be destroyed. The manager, I suppose considering the cost of replacing him, was not in favour of destroying him, and asked if I had any objection to trying him in slings for a week or so. Naturally, I had no objection, and by this time it was possible to get a few blades of grass to eat, which apparently did a little good, and if anything a slight improvement in his appetite took place for a week or so. This improvement was only temporary; he got gradually weaker, and was found dead in the slings one morning about the middle of May.

*Post-mortem.* I found multiple abscesses of a very large size all over the thoracic and abdominal cavities, particularly in the mediastinal glands. The kidneys were practically embedded in pus; the liver and mesenteric glands were full of abscesses; in fact I am quite safe in saying, and Mr. Brown, who was present at the p.-m., can corroborate my statement, the abdominal cavity was practically one mass of abscesses. What I cannot understand is how the animal lived for such a length of time with the internal organs in such a state.

I made enquiries afterwards as to whether the animal had ever suffered from strangles, as the abscesses resembled those found in bad cases of that disease. There was no history of the animal even having had a bad cold.

I will be very pleased if any of the members present can give me any enlightenment as to the probable cause of this condition. To me, as one of the younger members of the profession, it seemed rather an unusual case.

#### SEPTIC OR CONTAGIOUS MAMMITIS IN COW.

By R. E. DRENNAN.

This disease seems to be very prevalent at this season of the year, more especially in back calving cows, and in heifers running at grass even though not in calf.

The disease seems to start very suddenly in most of my cases, in fact animals have been quite well in the morning and by afternoon the symptoms had appeared, when one or two, perhaps all of the quarters of the udder were involved. I have had a good number of these cases under my observation during the last five or six years, more especially in the month of August.

The symptoms I am sure are very well known to all of you, but what I would like to know is if there is any special treatment, as my results in the badly affected cases have been very unsatisfactory; septicæmia has set in and the patients have had to be slaughtered.

The disease when the animals are at grass I am confident is due to a bite from a fly with a septic proboscis, inoculating the teat with a streptococcus. My reason for saying so is that I have tried preventive measures in several herds with excellent results. The method I adopt is to spray the udder of the animals twice a week, beginning about the middle of July, with a mixture of spirits of tar, sulphur and rape oil. In herds where the disease was formerly rife there has not been a single case since adopting this prophylactic treatment. Animals sprayed with this dressing seem to dislike the odour of the dressing. If infection has taken place, the treatment I adopt in severe cases, is to place the animal in a comfortable stall or loose-box and clothe well; give a saline drench to commence with and follow with stimulants. I apply fomentations to the parts of the gland involved three times daily, massage and draw the teat carefully as often as possible. I have tried injections of a warm 3% solution of boric acid, also a 5% solution of hydrogen peroxide, drawing out the fluid three hours after. This I repeat every three or four hours. My results with this treatment varied very much.

Hot fomentations, and rubbing the gland with extract of belladonna in vaseline, drawing out the discharge as often as possible, and after the subsidence of inflammation the inunction of iodine ointment is the treatment which has given me the best results.

Great care should be taken with the discharge drawn from the teats as it is a very dangerous source of infection to other cows which may be tied up in the same stall. I recommend covering the discharge with chloride of lime after each milking, and washing out the stall daily with a strong carbolic solution.

#### DISCUSSION.

Mr. McPHERSON said: We are all extremely indebted to Mr. Drennan for introducing these exceedingly interesting subjects for discussion. The udder cases interest me the most, as at this season of the year they are extremely prevalent and very difficult to treat, in fact, in my experience no treatment is of much use. I will be very glad to hear if any of the other members know of a successful method of treating these cases.

Mr. MURRAY: Like most of you I have had my share of these bad udder cases. I have tried amputation of the teat so as to allow free drainage, and give pot. chlor. as an internal antiseptic.

With reference to the horse case, I think probably a previous attack of strangles may have been the cause.

Mr. CLERK: I thank Mr. Drennan for his interesting papers, and would ask if the horse case was not one of tuberculosis.

In the udder cases, I have tried with varying results in the early stages carbolic soap liniment, and injection of warm Chinosol solutions.

Mr. BEATTIE: In these udder cases I find there is usually high fever. I give in some cases febrifuges and emollient applications to the udder. The infection, I think, is due to filth in the fields and byres. Cleanliness is the best preventive. I have not tried them, but I don't see why antiseptic injections should not help.

In the horse case, the disease was probably pyæmia, as a result of internal injury, or an injury to a foot. I don't think it was tuberculosis.

Mr. CUMMING: I am much obliged to Mr. Drennan for his communications. In case I. I note that the horse was ill weeks before he showed a rise of temperature: therefore I would be inclined to think that the horse received some injury during his illness causing septic infection. The case, if it could have been diagnosed, would have been a suitable one for serum treatment.

I have had my share of contagious or septic mammitis. I certainly believe that the infective agent is the fly or other insect. I have tried various treatments with different results. In the case of heifers I think the best procedure is immediate slaughter. I had recently a case in a heifer with five teats and, strange to say, the fifth or supplementary teat was the seat of the disease. I have never tried serums or vaccines. As a preventive there is nothing to beat dressing the udder with tarry liniments.

Mr. KERR: I am very much interested in the horse case as I had two cases recently, both of which died. On post-mortem the appearances were similar to Mr. Drennan's case. One of them was undoubtedly tubercular, while the other was septicaemia, with vegetations on the valves of the heart.

Mr. HEPBURN: In case I., I am inclined to think that the infection took place after the horse became ill. I had a fat horse which took ill with frequent attacks of colic. He died, and on post-mortem I found the lungs and mediastinal glands full of abscesses. He had been three years in the stud, and had shown during that time no trace of lung trouble, therefore I would suggest that he had got infected three years previously.

Regarding the udder cases, I have tried various treatment with indifferent results, I have tried injections with weak iodine solutions, but with no better results than by other methods. The best treatment in my opinion is to slaughter the animal. I believe the infection is streptococcal in origin and is carried from one cow to another by flies. It is sometimes suddenly fatal. I recommend as a preventive, Ung. petrol, Barbadoes tar, and Oil of citronella.

Mr. HOWIE: I had a case in a colt which, towards the end of the summer, got so emaciated that in the end he was unable to stand. I could form no opinion as to the cause of the trouble. Ultimately he died, and on post-mortem I found multiple abscesses in the abdomen, on the walls of the bowels, and in the mesenteric glands. In the pus I found numerous specimens of *sclerostomum tetracanthus*. On washing out the ingesta in the bowels I found millions of these worms, varying in length from  $\frac{1}{2}$  in. to 1 in., in the bottom of the bucket. I would ask Mr. Drennan if these worms were present in his case, as the p.m. appearances were somewhat similar, except that in my case the abscesses were confined to the abdominal cavity.

My experience of udder cases is that no treatment is of much use. A client who made a business of feeding farrow cows, in every case of septic mammitis, or, as he called it, "udder clap," at once amputated the teat of the infected quarter. This allowed free drainage, and saved a lot of trouble in the way of drawing the teat. I am bound to say his cases got on quite as well as mine. The best practice with farrow cows is to slaughter at once; for I don't know of any disease which picks the condition off a fat cow so rapidly.

Mr. BROWN, President: I was present at the post-mortem along with Mr. Drennan and found that the pus formation was generalised. It was undoubtedly pyæmia, but I am not prepared to attribute the cause. The pus was cold and not evil-smelling. I am inclined to think that the infection was of a long-standing nature. It might have been due to strangles, but the symptoms were not acute enough for that. It was probably due to infection through the bowel.

Treatment in the udder cases is very unsatisfactory. Injections don't do much good, they cannot get deep enough into the gland structure. Mammitis generally is worthy of investigation, as all varieties are not due to the same germ, hence the difficulty of treatment with stock serums. Autogenous vaccine might have good results. Regarding the removal of the teat, I know a farmer who lost two or three cows; after which he amputates the teats, with very good results. I think removal of the teats should be tried oftener than it is. I am of opinion that the disease is carried by fly infection and hot, moist weather. Dressing with tar, sulphur, and oil is very successful in keeping off the warble fly, therefore, I think it should be very useful as a preventive in these cases.

I have very great pleasure in asking you to accord to Mr. Drennan a hearty vote of thanks for bringing forward these two interesting subjects for discussion.

Mr. DRENNAN briefly replied, and thanked the members for their appreciation of his efforts to create a discussion.

#### ELECTION OF OFFICE BEARERS.

*President.* Mr. D. Clerk, Stonehaven.

*Senior Vice-President.* Mr. A. Kerr, Ellon.

*Junior* Mr. A. Niven, Inverurie.

*Hon. Sec. and Treas.* Mr. G. Howie, Alford.

*Council.* Messrs. Anderson, Crabb, McPherson, Sievwright, Murray, Robson, Drennan.

Messrs. Clerk and Johnston undertook to provide material for discussion at next meeting.

A hearty vote of thanks having been awarded to the President, the members adjourned to the Athenæum Restaurant for lunch and a friendly chat.

GEORGE HOWIE, Hon. Sec.

#### The A.V.C. Comforts Fund.

Dear Sir,—I am requested by the Committee A.V.C. Comforts Fund to ask you to express its most grateful thanks to Mr. King and to Mr. Willett for the great help they have both given in support of this Fund. Their time is fully occupied, but they have managed to collect about £400, which is nearly half the amount paid into the Fund's account since last July.

Mr. Willett's contributions were given in your last week's issue of *The Record*. May I ask you to be good enough to insert Mr. King's collections in your next publication?

Parcels have already been sent to Mesopotamia, Egypt, and Salonika, and it is hoped that bales for France and Italy will be very shortly despatched.

Owing to the very large number of men belonging to the Corps at present on the various fronts (over 17,000) it is, of course, impossible to send each man an individual Christmas parcel, but all subscribers may rest assured that the funds at the disposal of the Committee will be used to the best advantage.—Yours faithfully,

E. A. BLENKINSOP.

29 Bramham Gardens, S.W. 5.  
29th Oct.

All subscriptions will be gratefully received by  
Mrs. MARTIN, Hon. Treasurer,  
19 Stanhope Gardens, S.W. 7.

## ARMY VETERINARY SERVICE

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Oct. 26.

## REGULAR FORCES. ARMY VETERINARY CORPS.

The following Capts. are sec'd. for duty with Egyptian Army :—J. Going (July 16); G. V. Golding (July 21); C. P. Fisher (Aug. 8); W. H. Heaney (Aug. 10); J. R. Ellison (Aug. 11); G. E. Oxspring (Sept. 2).

## OBITUARY.

MALVISI.—At Hornsey, on 24th October, after four days illness, Emily Bertha Malvisi, the beloved wife of C. A. Malvisi, M.R.C.V.S. Aged 47.

Major JAMES EADIE DAVIDSON, D.S.O., Royal Garrison Artillery (died of wounds), was the elder son of Mr. and Mrs. William Davidson, 30 Garscube Terrace, Edinburgh. He was born in 1893, and educated at Daniel Stewart's College, and Edinburgh University, where he graduated B.Sc. in engineering in 1914. He joined the army soon after the outbreak of war, and had been on active service abroad since May, 1915, was wounded in the great German offensive in March last, and only a few weeks ago he received the D.S.O. He had also been awarded the Belgian decorations of Chevalier de l'Ordre de la Couronne and the Croix de Guerre.

Major Davidson was a nephew of Mr. C. A. Squair, M.R.C.V.S., of Reigate, Surrey.

CROWHURST. At Framfield, Sussex, on Sunday, 27th Oct., from pneumonia following influenza, Herbert Crowhurst, son of the late Thomas Crowhurst, Registered Practitioner, aged 38.

Deceased succeeded his father, with whom he had been associated in the practice, and had carried it on successfully. He was well known over a wide district and was much liked and trusted, and there were many following at the funeral who had come miles to pay their last respect. There were many wreaths and flowers. He leaves a widow and four young children.

In 1890 there were six Crowhursts in Sussex on the list of Registered Practitioners. At the present time only one remains, and the death of Mr. Herbert Crowhurst severs another link with the past.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1583.

NOVEMBER 9, 1918.

VOL. XXXI.

## A QUESTIONABLE PROCEDURE.

On another page we reproduce an odd paragraph from a provincial evening newspaper. It must be read with the mental reservations necessary with almost all newspaper information in these days; but, if it is correct, it is certainly disquieting. The gist of it is that the Ministry of Food has ordered a Commission to enquire into an "alarming mortality" in pigs in the Lincoln District. Some statements are added regarding this porcine disease, which are not very enlightening. We are told that the affection "appears to be epidemic"; and a belief that it is "a kind of influenza" is mentioned with apparent respect. This suggests some connection with the human epidemic now raging so widely; but veterinary pathologists will require some definite evidence before accepting such a theory as at all probable. It is further stated that the pigs almost always die of "inflammation of the bowels," which indicates that dietetic causes may not improbably be the chief or sole factors in its production. All this information is of much less importance than the single statement that "a Commission has been appointed by the Ministry of Food." Veterinary Surgeons will ask why the Ministry of Food acted at all in a matter which properly belongs to the Board of Agriculture.

It may be argued that the Food Ministry acted with the idea of preventing too serious an effect on the supply of pigs for food. This is not a sufficient reply. Government Departments constantly find their work bringing them into contact with subjects pertaining to other Departments; but that does not justify them in encroaching upon each other's ground. For Government Departments to communicate with each other, and assist each other when possible, is one thing; for any one of them to start doing the work of another is quite different.

The Board of Agriculture is the only Government Department fit to undertake the investigation of disease in farm stock. It possesses the staff of trained workers and the experience essential to the proper performance of such work. Its record for many years past shows that it is fully capable of performing first-class work in this direction. No other department could be relied upon to produce even second-class work; and no other should attempt such inquiries. Perhaps after all this report may prove to be a mere newspaper romance; but, even so, it suggests a very real danger, which the profession should be prepared to meet. We have had previous experience of this usurpation of the functions of the Board of Agriculture, notably by the Local Government Board. It is likely to increase in these days of multiplicity of departments; and the Food Ministry is certainly a sufficiently aggressive body to attempt it.

## FURTHER OBSERVATIONS ON SODIUM CHLORIDE.

By CAPT. W. W. LANG, A.V.C.

Six months further investigation confirms the results published in an article on Salt in *The Veterinary Record* of 23rd March, 1918.

The treatment appears to be quite satisfactory in catarrh, strangles, all wounds (operation: including castration, and accidental), cellulitis, suppurative lymphangitis, tetanus, and biliary fever. The explanation appears to be increased osmosis, and the elimination of the toxins which are believed by many to have a repelling action on the leucocytes. In the language of the day, the mobility of the defending force is greatly increased while the defences of the invaders are swept away.

In cellulitis, in addition to the rapid diminution of the oedematous swelling, a feature of great importance is the anodyne action—no explanation is offered; animals too stiff to walk and extremely sensitive to touch on the affected part move and tolerate manipulation freely within 24 hours. It would be interesting to know whether the same anodyne action is obtainable in laminitis.

In contused wounds sloughing appears to be reduced to a minimum and healing takes place rapidly. I have in mind two cases of badly broken knees, one of lacerated hock just over the bursa, and one of bruised and torn stifles through failing to jump clear over a wall with a tiled top—all might easily have ended fatally or necessitated destruction. In these, as in all others, no attempt is made to disinfect the wound; all that is done is to keep it and the surrounding parts clean, ensure drainage, and lightly cover with gauze to keep off flies.

In biliary fever, too, the period of convalescence due to the resulting anæmia and debility is also considerably shortened. The icteric symptoms vanish usually in two or three days closely followed by the petechial spots, as the result of saline in addition to the usual forms of treatment.

As our most valuable aid to putting on condition salt is absolutely proved. Lately, linseed and groundnut oil have been added with excellent results; the dose is one pint with half-a-pound of salt in two gallons of water daily—less oil tends to constipation, while the above amounts, in addition to their nutritive action, act on the fæces similarly to liquid paraffin. Neither purging, nausea, nor loss of appetite has been noticed—this applies to the normal dose of aloes, too—though the treatment has been continued for seven consecutive days decomposition of the oil appears to be pre-

vented. Sesame oil has not proved so satisfactory, perhaps on account of adulteration, as I believe it was purchased locally.

The lubricant action led to this method of using oil in cases of sand or grit in the colon, but as nothing eventuated, nux vomica has been added with a measure of success. Peristalsis appears to be considerably reduced in the dilated portion of the bowel containing the offending material—in one case of an animal which had "colic" ten times in two years the bowel was considerably thickened by fibrous tissue. So far, one ounce only of nux vomica has been given daily, but the dose may be increased with advantage.

Half-a-pound of salt appears to be a sufficient dose for all practical purposes, though in tetanus I give this amount twice during the first day's treatment. When an animal goes off his feed, as occasionally happens, the salt is withheld for a day, when the appetite as a rule returns. The practice is now to miss one day a week, usually Sunday.

Recently two animals have shown that they cannot tolerate salt, not even in six ounce doses, but these are the only two in probably a thousand cases.

#### ABDOMINAL SURGERY—WITH SPECIAL REFERENCE TO SODIUM CHLORIDE AND CHLORAL HYDRATE.

With a view to testing the value of saline in such cases, three horses down for destruction were operated on, one through the flank by splitting the muscles, and two through the linea alba, one in front of and the other behind the umbilicus. In the two latter the fore legs were pulled up by one pulley and the two hind by another, giving a free field.

Being without an expert anaesthetist and fully alive so the necessity for perfect anaesthesia, chloral hydrate 3iss intravenously was given to each with excellent results from an anaesthetic point of view, unconsciousness was complete for about one hour and a half.

All abdominal organs were freely manipulated to familiarise my sense of touch—this, of course, greatly increased the tendency to manipulative shock—while in the second case an attempt was made to evacuate a quantity of grit in the last portion of the double colon. This failed for two reasons:—on account of the mesenteric attachments the affected portion of the bowel could not be brought outside the wound for operation, while the narrow portion prevented the insertion of the hand. The bowel was incised in two places, but failure to remove more than a small quantity was the result. The operation was completed in the first by skin suture only, in the other two by suture of the abdominal wall and skin—suture of the peritoneum was not carried out, but it ought to have been done. In these two, before closing the skin wound a number of stiff wires were placed across the abdominal wound to lend support; the distance apart was one inch and a half, while each end was brought through the skin three inches on either side and turned round. As they were in no way intended as sutures about two inches of play

was allowed to each. The skin was punctured by means of the equine trocar and canula while the latter was used as a director for the wires. Unfortunately these two did not live long enough to prove or disprove the value of the method employed, but the impression of the support was good.

One of the latter, too, was badly affected with shock shortly after the completion of the operation, so half-a-pound of salt in solution was given while she lay, and she was warmly covered up. In the case of the other two the saline was given on rising, and a second dose to all about 8 p.m., and again next morning. All lay for about seven hours and were then returned to their boxes and tied up.

Every one of the three developed pneumonia (hypostatic)—the breathing was accelerated next day, but I attributed this to pain, while the temperature never rose above 104° F. The first, the flank case, recovered, but the other two died, one in 42 and the other in 48 hours. Post-mortem proved the existence of pneumonia; in one case there was little inflammatory action round the edge of the wound, while in the other there was rather more, but not much wrong with the bowel which had been incised. I attribute death in both cases to hypostatic pneumonia.

On discussing the matter with a medical friend I was informed that all narcotic poisons increase the permeability of the lung tissue and that, of course, the solution would further increase this action; also that the discharge of bloody urine (renal hæmorrhage), which I had noticed, was due to the narcotic.

Apparently the case of pneumonia which followed ovariectomy, which I mentioned in my previous article was brought about in the same way, and was not due to the entrance of saline into the lungs as I then thought. I now know that saline solution entering the lungs does not necessarily cause pneumonia; this will be discussed later.

In no case has pneumonia followed the intravenous injection of chloral hydrate or the administration of salt solution per os alone. Therefore, the combination in the doses given appears to be a dangerous one.

It may be that one to three pints intravenously, as recommended in "Veterinary Therapeutics" (Wallis Hoare), would be innocuous and suffice to ward off shock until the effects of the chloral hydrate have passed away. As an anaesthetic for abdominal work chloral hydrate as given appeared very satisfactory, and it required no watching, while the post-operative quiet of several hours must be of value.

#### ANIMAL HOSPITALS.

With the idea of animal hospitals throughout the country I heartily agree, I expect that the most important feature in the near future will be abdominal surgery. Too long have we looked on helplessly while an unfortunate horse has died a cruel death from twisted bowel, but I do not believe it is beyond the wit of man to combat many such cases. It is only a few years since tampering with the peritoneum was considered a fatal procedure;

now, rigs are operated on through the inguinal canal and the flank; ovariectomy is performed through the vagina and also the flank, while successful operations for the radical cure of hernia have been recorded. Those of us, too, who practice canine surgery are gaining experience not only of great value now, but valuable as a stepping stone to still greater things.

Operations under the best conditions, expert supervision, trained nursing, and a proper environment will bring to a successful issue what might otherwise prove fatal, and will make our successful cases more successful by restoring the patients to usefulness at a much earlier period.

#### STOMACH TUBE—DANGERS ATTACHED TO ITS USE. TRANSMISSION OF CONTAGIOUS DISEASE—VARIOLA.

Recently over 30 horses a day were under saline treatment for debility and various other conditions, most of them for a period of seven days at a time. Before it was quite realised what was happening, a few were found to be suffering from variola, and, as after events proved, many more were in the incubation stage—in artificial inoculation the incubation period appears to be five to six days. Altogether over 40 were ultimately affected, and all showed the lesions in the left nostril—that invariably used for the passing of the tube. We failed to detect the original case.

As it was imperative to continue the saline in several cases of variola, and also to treat others non-affected, the tube has since been immersed in a solution of perchloride of mercury, 1:1000 between each case—carbolic acid is not now on issue to veterinary hospitals. The perchloride solution was recommended as that least likely to injure the rubber, but it does not appear to be strong enough, or the period of immersion is too short, because two more cases have occurred. Naturally the non-affected were all treated first in the day. Now the need for treating variola cases for other conditions has passed away, and therefore no fresh cases as the result of the use of the tube are anticipated.

From the illustration it is evident that the tube should always be disinfected between each case as a matter of routine. It is indeed fortunate that it was the benign disease variola and not something more serious.

#### FLOODING THE LUNGS WITH SALINE.

Unfortunately, on three occasions the saline solution has been accidentally pumped into the lungs, once by an officer who ought to have known better, and twice by natives who were carried away by the apparent simplicity of passing the tube. Both the latter, in their anxiety to be of real assistance, passed the tube without permission in the temporary absence of the N.C.O. in charge.

It is remarkable indeed how these animals showed so little inconvenience while the tube was in the trachea. Recently, at a demonstration I personally kept the tube in the trachea for a considerable time without even a cough.

*Case I.* The quantity pumped into the lungs was estimated at 1½ gall. The temperature rose to

107° F. in the evening, but the animal was apparently all right the following day. No pneumonia supervened.

*Case II.* Had about a gallon of saline; temperature rose to 105° F; following day all right; no pneumonia.

*Case III.* This is the only one of three I saw. Had about a gallon of saline and a pint of linseed oil. Result—fatal.

The following is the clinical picture—I understand it was the same in all:—Lying on the chest with fore legs out; swaying the head and neck from side to side and at the same time rubbing the trachea across the knees; continuous flow of froth from both nostrils; deep, laboured breathing; cyanosed membranes; and apparently perfectly sensible.

From the description given to me of the other two cases, a fatal termination was not anticipated, so no treatment was adopted. Apparently the best treatment would be tracheotomy as low down the neck as possible.

The above incidents are reported so that others may profit thereby.

#### SEPTIC OR CONTAGIOUS MAMMITIS.

Mr. Drennan's paper before the North of Scotland Veterinary Society is greatly interesting, as this disease has been rather prevalent of late.

I venture to write my experience as regards treatment. The disease is most virulent, and causes a number of deaths, and usually it is the best milkers that are affected. I never hesitate, if the permission of the owner can be obtained, to amputate the teat or teats as early as possible; in doing this it is necessary to cast the cow, cut round the teat with the scalpel held in a line with the long axis of the teat. Any bleeding vessels can easily be tied with suture material.

The usual medicines are given, but I look upon them as almost useless unless free drainage is given to the udder, which is fomented and syringed out with weak Creolin, finishing off with 1:6 Hydrogen peroxide.

As the inflammation subsides the udder gets less and eventually the quarter atrophies; the wound usually heals completely.

These cows if bulled again are usually profitable milkers; but if operation is not performed either the cow dies or there is permanent enlargement of the quarter and disfigurement, with great risk at subsequent calving of another attack of mastitis.

As regards the killing of cows for human consumption when affected with septic mammitis, I venture to think it a great question if the carcass is fit for food, for the animal is seldom killed until the case looks hopeless, which means that it has had plenty of medicine and is a case of acute septicæmia with high temperature. The carcass is then a very bad colour and the fat does not set. Some may think the operation is drastic treatment, but if the operation is done under chloroform the relief given is great and can be quickly seen, whereas to leave the teat on and struggle to draw the secretion or

discharge three or four times a day from a hot and painful quarter is very unpleasant for the cow.

Operation, too, does away with the necessity of rubbing in liniments, etc., after fomentation, which unless carefully done must cause suffering to the animals, as they dislike lying down owing to the increased pain caused in the udder.

The use of vaccine as a curative in this disease is probably of not much service as the infection is so rapid.

G. E.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### THE LIFE-HISTORY OF *DISTOMA LUTEUM* (N. SP.) WITH NOTES ON SOME CERCARIE AND REDIE FOUND IN SOUTH AFRICA.

An article upon this subject by J. D. F. Gilchrist appeared in *Parasitology* for April, 1918. Although fluke disease in sheep is very common in certain parts of South Africa the intermediate host of the parasite has not been recognised. The fresh-water snail (*Limnaea truncatula*) which is the intermediate host in Europe has not been recorded with certainty in South Africa. The commonest fresh-water snail there is (*Physa Isidora*) *tropica*, and this mollusc harbours in great abundance stages of fluke very closely resembling those of the liver fluke, the important difference, however, being that even when placed in the most favourable conditions the free-swimming form (cercaria) was never observed to encyst.

The author's investigations proved that the forms found in this snail were in reality stages in the life cycle of a small fluke commonly found in the alimentary tract of the frog in South Africa. The adult form was very similar in appearance to *Distoma echinatum*, and on account of its colour it is named by the author *Distoma luteum*.

The problem as to the life cycle of the South African liver fluke thus still remains unsolved.—*Tropical Veterinary Bulletin*).

##### CHRONIC ARTHRITIS IN PIGS.

Sekiguchi and Ironse contributed an article upon this subject to Vol. 21 of the *Journal of Infectious Diseases*. Chronic arthritis, presenting various degrees of swelling and deformity, is not rarely observed in pigs brought to market, which are apparently in good health. These chronic lesions involve one or two joints. They may appear sporadically; or there may be various cases in the same piggery. By its character the disease much recalls arthritis chronica deformans of man, in which general symptoms of infection and nutritive disturbances are likewise often absent.

The authors were able to observe and follow 21 of these cases in pigs brought to market for sale. In these the arthritis varied in gravity from a simple enlargement of a joint to a notable thickening and deformity which resembled a chronic tubercular process in aspect.

By the microscopical examination of material from these cases the authors found bacillary microbes 17 times. In six cases in which streptococci were isolated, either alone or associated with bacilli, the lesions had a chronic suppurative character with fistulous channels, as in chronic tubercular lesions. A more accurate examination enabled tuberculosis to be excluded; as a matter of fact, the animals furnishing the material did not show tuberculous centres in any other part of the organism.

In nine cases the infection was purely bacillary. The lesions consisted, in the first stages, in a slight granulation upon the affected joint, and in advanced stages in a diffuse and grave process of ulceration with notable deformity of the joint. In some of these cases a limpid or slightly turbid but never purulent liquid was extracted from the joints. The liquid itself was completely sterile; and the bacteria were only found in sections and cultures prepared from the granulation tissue.

Morphologically, and in many points culturally, the bacilli resembled the *bacillus pyogenes* isolated by Dutch and German from cattle and swine, with the difference that the authors' bacilli did not liquify either gelatine or Löffler's serum. The same resemblance existed with regard to the pathological alterations. The latter were identical with those caused by the *b. pyogenes*; that is, they were of chronic suppurative character, with a tendency to the formation of granulations and fibrous tissue. The authors, however, never saw, either in the natural or the experimental disease, the pulmonary infections that are frequently found in animals infected with *b. pyogenes*.

Although in their cases the bacillus isolated was almost always the principal etiological factor and streptococcus only a secondary invasion, the authors do not venture to affirm that the bacillus is the unique infective agent of chronic arthritis in swine. It is possible that other organisms of suitable virulence may cause analogous processes in pigs; but the tubercle bacillus does not seem to be responsible for chronic articular lesions in pigs otherwise perfectly healthy.

The disease causes a not negligible damage even when the animals are brought to market in good general condition, and a much more serious one when it assumes an enzootic character. Studies on a larger scale and by more numerous workers are required to gain an exact and complete knowledge of its etiology.

The authors were able to produce articular lesions experimentally in pigs by subcutaneous and intravenous injections of the *b. pyogenes*. Hence it is possible that, in infected surroundings, the bacillus penetrates into the organism by means of some wound or lesion of the skin. The possibility of an infection by the digestive tract cannot be excluded; for in one case the chronic arthritis was accompanied by pronounced chronic lesions of the mesenteric lymphatic glands.—(*La Clinica Veterinaria*)

W. R. C.

# NORTH MIDLAND VETERINARY ASSOCIATION.

(NATIONAL V.M.A.—NORTHERN BRANCH).

A meeting was held at the Grand Hotel, Leopold Street, Sheffield, on Tuesday, August 27th. Prior to the meeting the members had tea together, at the invitation of the Sheffield practitioners.

The following were present at the meeting:—Mr. W. Collinson, South Anston, President, in the chair; Messrs. F. L. Somerset, Chesterfield; E. Marrison, Bakewell; T. C. Fletcher, H. Thompson, S. E. Sampson, S. H. Nixon, J. S. Lloyd, Sheffield. Visitors: Capt. R. M. Lawson, A.V.C., S.B., and Mr. E. A. Rucker.

Apologies for inability to be present were received from Mr. J. S. Wheatcroft, Wentworth; and others.

The minutes of the last meeting having been printed and circulated, were taken as read, and on the motion of Mr. Fletcher, seconded by Mr. Sampson, were confirmed.

The minutes of the Council meeting held on Aug. 6 were read by the Hon. Secretary, and on the motion of Mr. Fletcher, seconded by Mr. Thompson, were also confirmed.

Considerable discussion took place on the question of Veterinary Fees, the subject being opened by Mr. E. Marrison, of Bakewell, who was one of the signatories to the circular sent out by some of the practitioners of Derbyshire. Mr. Fletcher, in discussing the circular, thought that veterinary fees ought to be doubled, and proposed a motion to that effect. This, in the course of his discussion, was seconded by Mr. Thompson.

An amendment was proposed by Mr. Marrison, That a minimum of 50 per cent. advance be made on all charges. This was seconded by Mr. Sampson, and after being amended to be restricted to night visits, was carried.

The items in the circular were afterwards gone through seriatim; but upon coming to the question of medicines, the meeting decided that although the cost of drugs had considerably increased, seeing that practitioners varied much in the drugs used, it was not possible to fix definite charges. Members are therefore left to charge increased prices according to the drugs used.

It was pointed out that the Council of the National Veterinary Association desired the branches to discuss this matter of increased charges and to forward to the Secretary the results arrived at. It was consequently decided to adjourn further discussion of this matter until the next meeting.

The SECRETARY read an application for a donation to the Victoria Veterinary Benevolent Fund, and upon the proposal of the Hon. Secretary, seconded by Mr. Sampson, the Treasurer was instructed to send a cheque for two guineas to this Fund.

The question of members being called up for the army was next considered, and the Hon. Secretary was instructed to call a special meeting of the Association should any member be called up.

A short discussion then took place on a paper by the Hon. Secretary, on Swine-fever Serum Inoculation, postponed from the last meeting. Messrs. T. C. Fletcher, S. E. Sampson, and F. L. Somerset took part in the discussion.

It appeared to be generally agreed that the serum inoculation was successful in controlling outbreaks on infected premises by preventing the disease spreading to healthy pigs. It also enabled owners to re-stock their infected premises much earlier than if a full period of detention and isolation were enforced. Inoculation, however, since it was carried out only on infected pre-

mises, did little or nothing to prevent outbreaks of the disease occurring on other premises.

Mr. SOMERSET remarked on a practice of vaccination carried out in America, and, replying to the discussion, the Hon. Secretary remarked that what appeared to be necessary was a standardised virus to be injected into herds of pigs at the same time as serum inoculation was carried out. So far it appeared that a standardisation of swine-fever virus had not been definitely accomplished, as in connection with vaccination in America and in test cases in this country, a very considerable mortality had resulted amongst the herds of pigs vaccinated.

A vote of thanks to the Secretary for his paper was proposed by Mr. Sampson, seconded by Mr. Fletcher, and carried.

The next item on the agenda, namely, "Notes on interesting cases," by Mr. S. H. Nixon, Sheffield, was, with his consent, postponed to the next meeting.

A series of interesting specimens were then shown by several members. The President showed the fore-leg of a foal which terminated at the elbow; a rough calculus taken from the floating colon of a horse; a testicle from a yearling showing pus in the centre, and one from a "rig" which was found deep in the abdominal cavity but was apparently normal. He also showed a specimen of very well-marked shear-mouth in an old horse, one side being affected whilst the other side was normal. His interesting remarks in dealing with each specimen were much appreciated by the meeting.

Mr. SAMPSON showed the penis of a bull affected with papillomata.

A vote of thanks to the President for his specimens and for his conduct in the chair, and to Mr. Sampson for his specimen, brought the meeting to a close.

J. S. LLOYD, Hon. Sec.

## ANNUAL REPORT OF THE VETERINARY INSPECTOR FOR THE BURGH OF PAISLEY: 1917.

To the Provost, Magistrates, and Councillors  
of the Burgh of Paisley.

Gentlemen,—In conformity with the Public Health (Scotland) Act 1897, The Diseases of Animals Acts 1894–1917, and the Maintenance of Live Stock (Scotland) Order 1915, I have the honour to submit my Annual Report for 1917.

### Public Health Act.

For the year ending 31st December, 1917, I made 92 visits and examined 1551 milch cows. There were 15 cases with Chronic mastitis, not giving milk from affected quarters. One case of Indurated udder: on microscopic examination of the milk of this animal the result was found to be negative.

On the request of the Medical Officer I visited a farm and examined 24 cows with reference to the occurrence of Diphtheria on the premises. On the whole I found the animals in a very healthy condition.

During the year I seized in the Public Market under the Public Health (Scotland) Act 1897, four aged emaciated cows—two affected with General Tuberculosis, two with Tuberculosis and Johne's disease. Three of these animals were slaughtered and destroyed with the owners' consent: owing to a difficulty in finding owner of the fourth, a warrant had to be procured from a Magistrate for its destruction.

### Burgh Slaughter House.

During the year I examined 211 carcasses:—Cattle 195, Sheep 12, Swine 4. Of these, 46 carcasses were passed; 165 were condemned as unfit for human food. Weight of meat condemned—32 tons, 16 cwt., 0 qr., 8 lb.

*Diseases of Animals Act.*

As usual, weekly visits were made to the Cattle Market, and all cattle, sheep, and swine exposed for sale were examined by me to prevent sale of any visibly diseased animals. The numbers examined were: Cattle 16,208, Sheep 23,903, Swine 173.

58 licences were granted for the removal of 173 swine from the Market to various slaughter houses; and 41 licences admitting 124 swine into the Burgh.

During April there was a reported outbreak of Swine fever, necessitating the examination of 17 swine which had been in contact with a pig that died of the disease. Notice prohibiting their removal was duly served.

*Maintenance Order.*

In accordance with this Order 110 in-calf cows were examined and found to be affected as follows:—Defective udders 100, Chronic mastitis 7, Tuberculosis of the udder 2, Rheumatism of hock joints 1. These animals were slaughtered under licences.

Veterinary attendance on Corporation horses necessitated 80 visits.

In the month of September I had three garden plots of potatoes destroyed at the Destructor owing to their having wart disease.—Your obedient Servant,

ANDREW MCGEOCH, M.R.C.V.S.,  
Veterinary Inspector.

## THE CLINICAL THERMOMETER ORDER.

The *London Gazette* of October 11 published the following Order, which is of considerable importance to Veterinary Surgeons:—

The Minister of Munitions, in exercise of the powers conferred upon him by the Defence of the Realm Regulations and all other powers thereunto enabling him, hereby orders as follows:—

1. On and after October 21, 1918, no person shall sell, offer for sale, supply or deliver any clinical thermometer which has not been tested, approved and marked, in accordance with the undermentioned rules, or any other rules made from time to time by the Controller of Glassware Supply on behalf of the Minister of Munitions and for the time being in operation.

2. This Order may be cited as the Clinical Thermometer Order, 1918.

3. All applications with reference to the above Order should be made to the Controller of Glassware Supply, Ministry of Munitions of War, 22-23 Hertford St., W. 1.

## RULES.

(1) Before any clinical thermometer is sold, offered for sale, supplied, or delivered, the same shall be forwarded carriage paid to the Director of the National Physical Laboratory, Teddington, for testing and approval.

(2) For a period of one month after the date of the Order, no thermometer showing at any point in its registration of temperature an error of more than .4° F. will be approved. On the expiry of this period, no thermometer shall show an error exceeding .2° F. over the range up to 106° F. Above this temperature the error shall not exceed .3° F. For thermometers graduated in degrees other than Fahrenheit, corresponding tolerances will be allowed. A thermometer will not be approved if it is not self-registering with a constriction, which must be such as to retain the index column and allow of the mercury being reset.

(3) Approved thermometers will be marked with the National Physical Laboratory trade mark and the year

of test, thus:—**№ 18.** The charge for testing the thermometers will be 3d. (three pence) per instrument, payable in advance to the Director of the Laboratory, this charge to cover return carriage upon the instruments to any place in the United Kingdom and also insurance against loss or damage in transit both ways and during test at the Laboratory. All thermometers submitted for testing to the Director must be clearly engraved with a distinctive number. Thermometers not already so engraved will be engraved at the Laboratory at a charge of 1d. (one penny) per instrument, payable in advance to the Director.

NOTE.—The National Physical Laboratory is prepared to issue a certificate setting out details of the results of the prescribed tests in regard to any thermometer which is approved in accordance with the above rules, on payment of an additional fee, particulars of which may be obtained from the Director of the Laboratory.

Cheques, etc., should be made payable to the Secretary, Department of Scientific and Industrial Research, and should be forwarded to the Laboratory. Cheques, etc., should be crossed "Bank of England a/c His Majesty's Paymaster General."

All applications with reference to the above Order should be made to the Controller of Glassware Supply, Ministry of Munitions of War, 22/23 Hertford Street, London, W. 1.

The foregoing Order as it stands would have made it impossible for doctors and veterinary surgeons to obtain a clinical thermometer on or after October 21, inasmuch as on and after that date it would have been illegal to sell any clinical thermometer not tested, approved, and marked in accordance with the rules made under the Order, and on and after November 11 no thermometer showing an error of more than .4° F. would have been approved. Under these circumstances the Pharmaceutical Society made urgent representations to the Controller of Glass Supply as to the imperative need for an extension of the period of grace, the result being that the Controller has made the following concessions:—

(1) No steps will be taken to enforce this Order until November 21.

(2) The period during which clinical thermometers will be approved if they show an error of no more than .4° F. will be extended so as to include those received at the National Physical Laboratory on or before November 21. This concession, however, applies only to stocks held on the date of the Order (October 11) by dealers other than manufacturers.

Veterinary Surgeons are warned not to purchase after October 21 any thermometers that have not been verified.

F.R.C.V.S.

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:— (Oct. 19; Nov. 5).

William M. Ferguson, Dundee	£1	1	0
F. C. Scott, Capt. A.V.C.	1	1	0
C. E. J. Meikle, Sunderland	1	1	0

## ARMY VETERINARY SERVICE.

Buckingham Palace, Oct. 31.

The King held an Investiture in the Ball Room of the Palace at 10.30 o'clock this morning. The following were introduced into the presence of the King, when His Majesty invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted:—

THE MOST DISTINGUISHED ORDER OF  
SAINT MICHAEL AND SAINT GEORGE.

COMPANIONS:—

\* \* \* \*

Colonel ERNEST KENDALL, Australian Vety. Service.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Nov. 2.

REGULAR FORCES. ARMY VETERINARY CORPS.

To be temp. Lieut.:—J. B. A. A. Dufresne (Aug. 27).

Dir. of Vety. Servs.—Temp. Maj. (actg. Lt.-Col.) C. E. Edgett, D.S.O., Can. A.V.C., from Asst. Dir. of Vety. Servs., and to be actg. Col. whilst so empld. (Aug. 6).

Nov. 4.

Temp. Qrmr. and Lt. E. A. Germany to be Capt. under Art. 330, R. Wt. for pay and promotion (Oct. 13).

Nov. 5.

To be temp. Lts.:—J. L. Millar (Aug. 27); H. H. Leach (Oct. 21).

TERRITORIAL FORCE, ARMY VETERINARY CORPS.

Oct. 29.

Capt. (actg. Maj.) F. W. C. Drinkwater relinquishes the actg. rank of Maj. on ceasing to be empld. as A.D.V.S. (May 1).

Capt. J. J. Ridley to be actg. Maj. while empld. as D.A.D.V.S. (Oct. 10).

## VETERINARY FEES.

To the Editor, "The Veterinary Record."

Dear Sir,—I am a Veterinary Inspector in a country town (Borough) of 12,000 inhabitants. I attend 26 cattle markets and 4 fairs in the year, carry out the sheep dipping orders, and all other duties of a Veterinary Inspector. I am also Inspector of Meat—about 1300 beast, 2100 sheep, and 800 pigs yearly—and this takes up two half-days and several casual visits on other days each week.

I am also Inspector of Milk Shops, Dairies, and Cowsheds—about 40—and about 180 cows, and these are inspected monthly, except that the cowsheds are missed in the summer months, when the animals are at grass.

I succeeded another veterinary surgeon in the appointment 10 years ago, and the total annual salary is £60, which I am inclined to think is too small.

If this is in accordance with the pay for similar appointments elsewhere I can hardly think it offers much inducement to our students to take up this branch of our profession, and I should be obliged if any members of the profession could enlighten me as to salary paid for similar duties elsewhere, so that, should I apply for an increase, I may be able to give instances of better terms—of which I have no information at present.

I am, yours faithfully,

F.R.C.V.S.

## "CASTING SHADOWS BEFORE."

Dear Sir,—Your editorial note in the current issue of *The Veterinary Record* is full of reflection and possible suggestion. Your reference to the communications which have already passed between the Council and the Government concerning the re-settlement of veterinary surgeons in civil life after the war appears most timely.

To my mind this is a problem which will require the utmost sympathy of the members who stayed at home. I have no inkling of the views of the Council, or of the Department which is entrusted with reconstruction, as to the procedure to be adopted in the case of our profession, but I think a scheme might be evolved whereby deserving members should be able to start in partnership with the minimum of anxiety on the eternal question of ways and means.

Everyone is aware that the average Captain A.V.C., who joined up in the early days of the war has not been able to save a lot of money, while simultaneously he has lost his practice which provided a living for him and his wife and family in pre-war days. Therefore it is up to the profession to help all deserving members who desire to practise at home.

I think a workable scheme might be formulated on lines whereby the payment of a peppercorn premium, say of £100, would guarantee a half share in a practice of a minimum of £275 p.a. net for two years, and a maximum of half share of the profits p.a.; at the termination of two years the working expenses to be equally divided between the partners. By that time a deserving man would by his industry and integrity have established a certain *locus standi* in a district.

Perhaps the foregoing bald suggestion may seem at first sight to be Utopian, but the world is not what it was in July 1914.

If this question is tackled in a right spirit by the authorities, those who lost practically all on mobilisation ought to be started again if willing to adapt themselves to altered conditions; and, in my opinion, the department which deals with reconstruction after the war should provide funds which would enable some of our members to start practice again on demobilization.

Yours faithfully, F.R.C.V.S.

## Personal.

Sir WILLIAM HENRY THOMPSON, M.D., who was drowned by the torpedoing of the "Leinster," was scientific adviser to the Ministry of Food and one of the oldest members of the staff.

He was Professor of the Institute of Medicine in Trinity College, Dublin, and a recognised authority on dietetics and the physiology of nutrition, in connection with which he carried out important investigations having special reference to food values.

The deceased, who was an honorary member of many British and Continental Medical Societies, was made a K.B.E. in 1917. He was Examiner in physiology to the Ryl. Coll. of Vety. Surgeons.

Mr. A. I. MACCALLUM, M.R.C.V.S., J.P., Edinburgh, has resigned from his position of Vice-Chairman and Life Member of the Board of Management of the Royal (Dick) Veterinary College, owing to the affairs of the College "coming between him and his sleep." The Board has elected him Honorary Life Member.

Mr. MacCallum delivered a lecture at Maybole (his native place), on 18th ult., on "Diseases of Animals common to Man," and dealt at length with tuberculosis, anthrax, glanders, and rabies.

So far there has been no award of bursaries for which Mr. MacCallum gave £2000 towards defraying the cost of education of students who enter the Dick College from certain parishes in Ayrshire.

**BACTERIOLOGY.** At the annual meeting of the Ross Memorial Hospital, Dingwall, Mr. GEORGE GAIR, M.R.C.V.S., Conon Bridge, who has been doing this class of work for the past few years, was appointed Bacteriologist to the hospital, including the county fever wards. Mr. Gair has made a special study of the subject in Edinburgh Royal Infirmary during the past five years, and has written several contributions to leading medical papers.

### Sheep Diseases.

At the annual meeting of the Cheviot Sheep Society held at Hawick, it was decided not to take any action in connection with a communication on the subject from the Glasgow Veterinary College, in view of the investigation inaugurated by the East of Scotland College of Agriculture into sheep diseases.

In the House of Commons.—Answering Mr. Hogge, Mr. Monro (Secretary for Scotland), in a written reply, says: An investigation into diseases affecting sheep, including louping-ill, is at present proceeding at the Glasgow Veterinary College, and the relative expenditure is being met by the Board of Agriculture for Scotland from the Agriculture (Scotland) Fund. A similar

investigation was begun at the Royal (Dick) College, Edinburgh, but has been suspended meantime, as those engaged in the research have been called up for service with the Army Veterinary Corps.

### "Strange mortality in pigs."

The Ministry of Food has ordered a Commission to inquire into the alarming mortality in pigs in and around Lincoln, which continues unabated. The disease from which the animals are suffering is a mystery. It appears to be epidemic, and much credence is given to the theory that the porkers are being visited by a kind of influenza. Death is almost invariably found to result from inflammation of the bowels. Whatever the disease may be it is very swift in its operation.—*The Bolton Evening News*.

### OBITUARY.

R. M. HAMILTON, M.R.C.V.S., Castleblaney, Co. Monaghan. Graduated, Glas: April, 1886.

Mr. Hamilton's death occurred at his residence, on Tuesday, Oct. 22nd.

BERNARD ALLAN SEARBY, M.R.C.V.S., Ramsey, Hunts. Edin: May, 1909.

Mr. Searby died 29th October.

## SECONDARY AND MIXED INFECTIONS.

Few pathological subjects have advanced so greatly in importance in the last quarter of a century as "mixed infections" and "secondary infections." This is more especially the case as regards secondary infections in specific diseases. In the eighties and early nineties the importance of these was underrated by most pathologists, and quite disregarded by many clinicians. Their occurrence was recognised, and the possibility of complications of specific disease arising from them was realised more or less vaguely; but very few even suspected the frequency and gravity of such complications.

To-day, every clinician can name specific diseases in which secondary infections are or may yet be proved to be most important complicating factors. Swine fever and canine distemper are perhaps the most striking examples; and what is known as "foot-and-mouth disease in a malignant form" is another. Strangles may ultimately fall into the same class; for it is quite possible that the streptococcus of Schütz, which was once universally regarded as its definite cause, may prove to be merely a secondary infection. A note which we printed a fortnight ago suggests that secondary infections may assume a hitherto unsuspected importance in epizootic lymphangitis. It has been thought that the unopened lesions of this disease were caused by the specific cryptococcus alone; but Carpano's researches cast considerable doubt upon this. He found pyogenic germs associated with the cryptococcus in practically two-thirds of his fairly numerous cases; and there is much to be said for his view that their influence upon the disease "cannot be negligible." These are only a few examples; every practitioner could cite others.

All these questions of secondary and mixed infections are of great importance. Pathologists everywhere are now studying them closely; and all clinicians should follow their results. Secondary infections are important enough as regards their influence upon the course, symptomatology, and prognosis of disease; but they are equally, if not more important from a therapeutic standpoint. Carpano points out their bearing upon the therapy and immunisation of epizootic lymphangitis; and the same truth holds in the case of other diseases. This requires no emphasis in these days when specific therapy, both biological and chemical, is coming more and more to the front. The success of such products as phylacogens, Leclainche and Vallée's polyvalent serum, illustrates the importance of mixed and secondary infections in therapeutics.

## B.I.P.P.—DEPOT TREATMENT OF WOUNDS.

By F. T. HARVEY, F.R.C.V.S.

In August, 1916, Prof. Rutherford Morrison, Northumberland War Hospital, introduced to the surgical world, Bismuth Iodoform Paraffin Paste, as a dressing for wounds, and suggested "Bipp" as a suitable name for the combination. We at once began treating wounds after the method of Morrison, and have continued to do so. Having thus had more than two years' experience of the use of the paste, it may not be out of place to direct attention to the matter in the pages of *The Veterinary Record*.

We do not remember to have seen any articles from veterinary surgeons dealing specially with B.I.P.P., and from inquiries made, it would appear that it is not largely used in veterinary surgery—at least in civil practice.

It may be said at once that the influence of Morrison's paste on the condition and progress of a wound is simply wonderful. It is a method of treatment which lends itself more particularly to the surgery of the farm and field, and we regard it as *par excellence* for wounds—those involving the bones, joints, and feet in particular. In advocating a new treatment, it is particularly necessary—in the words of Prof. Morrison himself—to avoid over-estimation from excess of enthusiasm, but we have never seen any results with the various wound dressings employed from time to time, at all comparable to those obtained when this form of paste has been used.

B.I.P.P. is composed of sub-nitrate of bismuth one part, and iodoform two parts, with sufficient liquid paraffin to make a thick paste. It is best freshly prepared, and the paraffin can be added to the mixed powder as required, care being taken to see that it is thoroughly incorporated and contains no lumps. Any consistency may be made, but the most useful are those of soft butter and thick cream. According to Drs. Helen Chambers and J. N. Goldsmith, the bactericidal action of Bipp results from the free iodine liberated from the oxidation of iodoform by oxygen, and by the nitric acid formed by the hydrolysis of bismuth nitrate. The decomposition occurs somewhat slowly in the wound, inhibits bacterial growth, and exhibits no irritating effect on the tissues; on the contrary, sedative effect seems to be produced, as indicated by the apparent absence of pain in the wounded part.

*Toxic properties.* In man it is not considered safe to use more than two or three drachms of the paste, and canine and feline patients should receive

correspondingly small amounts of dressing. We have used a drachm on a cat without bad results. There is no need to run any risks in these patients, as a little of the paste goes a long way with both dogs and cats. Poisoning either with bismuth or iodoform is not likely to occur in our larger patients, but even in these, very heavy dressings will be rarely necessary except in extensively contused wounds. We have so far never had reason to suspect the occurrence of any toxic effects, though such have been noted in man.

By way of illustration, it may be interesting to indicate a few of the types of wounds in which the treatment has been applied.

#### BROKEN KNEES.

We allude to those knees in which the injury is severe, and up to any degree actually short of fracture. The ligaments are torn, bone exposed, and joints open; in fact, there is extensive disorganisation of the face of one or both knees. In such cases the size of the skin wound will give no indication of the extent of the damage beneath, for this will only be evident after the parts have been laid open. The earlier these wounds are dealt with the better, for if left over forty-eight hours before treatment is properly taken in hand good results can hardly be expected.

*Treatment.* Soak the wound with tincture of iodine and cover with cotton-wool while the leg is being cleansed. Hair may be removed as desired. Explore the wound with a finger, having first well soaked the latter in iodine tincture. Cut the soft tissues through in the middle line in order to obliterate all pockets and any nooks likely to form so-called dead spaces, and thus establish drainage, and further enable the tissues to extrude any particles of grit which may have been overlooked at the first dressing. Again soak the parts thoroughly with the iodine solution, including the skin around the wound. Get the wound cavity as dry as possible, and then give every part a thorough dressing of of Bipp; this latter should be gently rubbed in. (Sterilised rubber gloves are supposed to be used when handling the wounds, but we have always relied on the bare fingers after well soaking them in the iodine tincture). An excess of paste may be left in the wound; the latter is then well covered with gauze or cotton-wool and a bandage applied. Time is well spent in doing all this, for unless the first dressing is carefully carried out the subsequent history of the case will be disappointing. Prof. Rutherford Morrison sums this up by saying that a clever surgeon is unnecessary in treating wounds, but that a careful one is highly desirable. If the knees are very badly damaged the wounds may be inspected on the second and third days, the discharge mopped up and any grit removed, and a little more paste may be lightly applied; and if this is done, the gauze or tow is best soaked in hot paraffin, either liquid or soft, as it does not then stick to the wound; moreover, gauze thus treated hinders coagulation of blood and lymph, favours drainage, and retards putrefaction. No bathing or washing of the wound is attempted.

After the third day the dressing is not disturbed, and beyond keeping it in position, nothing need be done for a week or more. There should be practically no swelling, pain, nor discharge. The greatest care must be taken not to break down adhesions formed in the depths of the wound by any late deep applications of the paste. Any infection of the wound at this stage will probably take place from the surface or skin margins, and these can be guarded against. The wounds sometimes look rather dirty when opened, but they will probably be clean surgically.

One knee recently treated had a good deal of grit ground into the tissues, and the bone exposed. It was dressed twice only in twenty-seven days, by which time healing was practically complete. The knee was never bandaged, the cotton wool having stuck on, remained dry, so was not disturbed. Ancillary treatment in these cases, such as the use of slings, immobilization of the joint, exercise, etc., must be left to the discretion of the practitioner. Peroxide of hydrogen is excellent in later stages, when the wound is granulating.

#### WOUNDS IN THE REGION OF THE STIFLE AND ELBOW JOINTS.

Contused, jagged wounds in these part are often caused by the animal being dragged or forced along a hard and rough surface. The skin is ground through, the subcutaneous tissues are torn widely, the fascial planes often more or less damaged, and in some cases the articular cavities may be open. Several areas, perhaps are injured, and all will have grit, earth, and stones ground into the tissues. Such wounds are particularly prone to sepsis, and when once thoroughly infected are most troublesome and unsatisfactory in many ways, and if septic arthritis supervenes a fatal termination is common enough. The Bipp treatment has given us excellent results. After the dressing is applied, some cotton-wool or gauze is put on, and little after attention is usually required. The absence of pain, discharge and swelling is notable, and healing of the parts proceeds apace. The usual diurnal antics of bathing, lotioning, twitching, etc., worry the animal no longer, and the wounds repair under more congenial conditions than of old.

In regard to the draining of these wounds; opening or bottoming the main cavity is sometimes not enough. Smaller pockets may exist deep down in the wound, especially when the fascia has been damaged. Any such partially torn tissue should be divided, otherwise tension may occur, blind spaces remain, and a septic condition be promoted.

#### WOUNDS IN THE ORBITAL REGION.

Injuries here are peculiarly suitable for the application of the treatment. Wounds in the temporal fossæ are difficult to drain and a bacterial invasion of them not infrequently becomes a matter of gravity.

A cob received a kick penetrating the soft tissues and injuring the bone above the left eye. We saw the case about thirty hours after the infliction of the injury. The parts were very painful and

swollen, the eyeball was invisible and the wound looked angry, with some oozing of serum; the orbital fat was inclined to come outside, after the fashion of a hernia cerebri. Two small pieces of bone were removed from the depths and the external wound was enlarged. The usual Bipp procedure followed, care being taken to get the paste well down into the cavity. The owner was instructed to re-bipp on the second and third days. We saw the case again on the fifth day and found the improvement marvellous. The swelling had gone, the eye looked natural, the fat had receded, and the wound was closing and almost dry; little subsequent attention was needed.

#### WOUNDS ON JOINTS GENERALLY,

Horses, in particular, often get kicked or stabbed close to a joint. The wound is frequently small and unimportant-looking. The owner fomented and rubs in somebody's special cure-all or embrocation, or something of the kind, with the remark that "That's nothing; it will be all right in a day or two." The so-called treatment is continued daily, and on the third or fourth day the animal is found standing on three legs, and the case becomes one of septic arthritis. Now if these cases were managed somewhat after the manner we have indicated above, they would practically all heal without the slightest difficulty—as we have often satisfied ourselves. The fact that the joint has been opened is by no means a bar to a happy issue; the trouble being that these cases so often do not come under the purview of the veterinary surgeon until a severe sepsis has been brought about.

How do these liniments and extracts, or whatever they are called, bring about a septic arthritis? Sir Almroth Wright, in discussing the effects of irritants on wounds generally, says: "There is produced—and this applies quite generally in connection with every application which irritates the skin—first reddening of the epidermis: then effusions and blistering; and then there develops in the blisters a luxuriant growth of serophytic microbes. In other words, by our misdirected energy we cultivate at the very doors of our wound, upon the very area of skin which we intend to keep free of microbes, a copious harvest of streptococci and staphylococci."

In connection with these wounds, it is interesting to note some of the characteristics of joints, and their behaviour towards infection and treatment: "Most joints are lined by synovial membrane. This possesses, in common with other serous membranes, two important characteristics on which all successful treatment is based—namely, (1) an extraordinarily strong capacity for overcoming septic infection; and (2) an equally strong capacity for forming adhesions. These adhesions form with considerable readiness; at the end of twenty-four hours they are very well marked indeed; sometimes they may form within several hours. As a result of this capacity for forming adhesions the advent of sepsis from without is largely prevented, and any sepsis inside the joint may remain localised for a considerable time, granted that the exudation

poured out has a free exit. It is largely in consequence of these two characteristics that joint lesions are now regarded as of much less surgical importance than was thought to be the case several years ago, granted that the wound is efficiently treated within a reasonable time of its infliction."—"Gunshot Wounds of Joints," J. Campbell, *Lancet*, Oct. 9, 1918.

"Dressings should be changed as infrequently as possible, for two reasons: (1) the risk of movement, and (2) the risk of fresh infection from without. This latter is a matter of prime importance where it has been impossible to close the joint cavity and sew up the wound. For these cases it seems best to use Bip paste in preference to any other method of wound treatment, even the Carrel Dakin one."—*Idem*. "The value of Morrison's Bip paste in wound treatment would appear to be completely established,"—*Idem*.

*General remarks.* There are three principal methods of treating infected wounds at the present time, each having its champions and followers. Each of them seems to be specially adapted to fulfil certain requirements, and they may be generally indicated by the terms "Wrightism," "Carrelism," and "Morrisonism," and they are all outgrowths of the older "Listerism."

#### WRIGHTISM.

Sir Almroth Wright and his followers maintain that diminution of sepsis and healing of wounds can be most readily attained not by the application of bactericidal substances from without, but rather by utilising the bactericidal bodies normally circulating in the blood and lymph. They say that aerobic and anaerobic organisms are present in the nooks and crannies of wounds, in positions quite inaccessible to any antiseptic solution applied from without, but readily destroyed if sufficient bactericidal bodies can be brought into contact with the same by the lymph stream. In other words, "lymph lavage" is the all-important factor in the treatment of septic wounds. It is the physiological system, and has also been termed the "concentrated saline school." It involves more or less continuous irrigations with so-called hypertonic or salt solutions. Free drainage and hot fomentations are important parts of the treatment; and it involves a good deal of attention. In some cases it produces excellent results in veterinary surgery. There is one phrase used by Wright to which attention may be directed, and it refers to "lymph-bound" wounds. We all know the tendency in some horses for their legs to swell when standing in a stall, and any wounds existing in such cases may then become, in Wright's words, "lymph-bound." A wound may get into such a condition apart from the presence of bacteria. Such limbs are bad healers, and favour cellulitis, as is the case in the presence of all stagnant lymph. We thus explain the benefit of exercise and "physic" in certain wounds in the horse. The late William Hunting paid some attention to the condition in a paper on "Swelled Legs."

Wright's work has been of considerable value in

pointing out the importance of good lymph circulation in wound repair, and it has many applications in practice.

One of our earliest remembrances is that of seeing wounds washed with salt and water; we also once saw a horse that had been down and cut his knee, being taken into the sea for a swim; and we have been told that this form of bath was not infrequently carried out in the middle of the last century.

#### CARELLISM.

The new antiseptic school is to-day focussed in the hypo-chlorite group, of which Dakin's solution and "Eusol" (Lorrain Smith) are the types of fluid used in flushing wounds. Carell is the high-priest of the method, and holds that if sepsis occurs or continues in any wound it is the fault of the surgeon. The wounds are continually flushed, and where this is impossible the flushing is carried out at two-hourly intervals night and day; the septic material is carried away and a sterilisation of the tissues obtained. Carell's tube treatment is very popular, and shares with Morrison's paste the largest amount of patronage amongst the various methods of wound treatment at the present day. It seems most suitable for hospital cases as it involves a good deal of attention. There is a very good paper on the subject in the *Veterinary Journal* for April, 1918, by Captain E. S. W. Peatt, A.V.C. The hypo-chlorites are very powerful disinfectants and yet do not irritate the tissues. The technique is one the ordinary farm attendant will fail to carry out as a rule, and disappointment will consequently follow; one of our knee cases went wrong in this way, and septic arthritis resulted. These fluids are, however, of great use in many cases, such as foul, sloughing wounds, and they are cheap and easily prepared. Youatt frequently advised the used of chloride of lime. As showing the difficulty of sterilising an infected wound it has been found that actively multiplying germs may be present on the surface of such a wound within thirty minutes of the application thereon of tincture of iodine or peroxide; the organisms coming up from the deeper layers.

#### MORRISONISM.

The "Dépôt action" of antiseptics has been used more or less in wound treatment for many years. Lister's double cyanide was placed in wounds by some surgeons, while others used iodoform, the object being to obtain a slow and continuous generation of antiseptic in the wound which will ultimately lead to a local sterility, or, so inhibit the growth of organisms therein that they are rendered harmless. The method involves (or should) infrequent dressings, and a minimum disturbance of the patient with a corresponding saving of labour. Moreover, the danger of re-infection of the wound—always present with frequent dressing—is greatly lessened, and it is the latter point which assumes such an important aspect in veterinary surgery, especially in large farming districts where the patients are often far afield. A system of treat-

ment then, where a surgeon can dress the wounds how and when he pleases, and wherein a day up or down, in removing the dressings or inspecting the wound matters little in the ultimate result, must necessarily possess many attractions, and of all the substances so far used none has given such good results as the Bismuth Iodoform Paraffin Paste, as introduced by Morrison.

#### OBSERVATIONS ON JOINT-ILL PROPHYLAXIS.

Much has been said and written of late concerning this equine malady, and veterinary practitioners as well as breeders throughout the country welcomed the news that a Committee of Investigation had at last been appointed to ascertain, if possible, the specific cause and a remedy. Practising as I do in a district in Scotland where a large number of valuable Clydesdale foals are bred every year, I encounter a great many cases each season.

At the outset I have to admit that I have been grievously disappointed with my results in the treatment of joint-ill. I have tried all the time-honoured therapeutic agents—internal and external, but my results in a large percentage of cases were far from encouraging. This season I decided to take up a preventive line of treatment on a large scale.

In our present stage of investigation diversity of opinion still exists as to whether joint-ill is entirely pre-natal or post-natal. Without favouring either theory in its entirety, I decided to treat the mare during pregnancy, and the offspring immediately after birth.

In the early spring of this season Messrs. Parke, Davis & Co. kindly offered to place at my disposal an unlimited supply of their Polyvalent Antistreptococcic Serum for the prophylactic treatment. 14 c.c. of the serum was injected hypodermically into each mare in the usual fashion on or about the tenth day before the expected date of foaling, and 14 c.c. was injected on the third day before foaling. 7 c.c. was injected to the foal 24 to 48 hours after birth.

Sixty in-foal mares were similarly treated with the Polyvalent serum, and during the whole season not a single case of joint-ill was observed in the foals of the injected mares. Seventeen of those mares had foals showing joint-ill on one or other of the two previous seasons.

As I was unable to undertake all the work, a large number of the mares in the district were not injected, and in four of these cases the offspring developed joint-ill which proved fatal.

The mares received no special treatment and were foaled in the usual foaling boxes. As is my usual practice, the umbilical cord was painted with Tr. iodi.

It was advised to inject the foal on the eighth day after birth, but I considered it more rational to treat the foal as soon after birth as was possible.

In one well-known Clydesdale stud we managed to secure sixteen fine foals from sixteen mares—

three or four cases of joint-ill had been usually encountered here each season.

A fact which struck me in every case, and which appears to me to be very significant, was that every mare carried her foal a fortnight, and in many cases three weeks past her actual foaling period. The foals were born strong, with a thick coating of hair, and in most cases the umbilical cord ruptured naturally and did not require to be ligatured.

Eight different stallions were the sires of the foals; and in this connection I would say that two seasons ago a well-known stallion travelled in the district which had been affected with pink-eye the previous winter. Although all the mares which he served showed typical equine influenza symptoms shortly after service, the mares produced healthy foals, and in no case was joint-ill seen as a result. This, I think, is also of some little note, as it has been asserted by some authorities that joint-ill symptoms and cases of fistulous withers have been frequently observed in the progeny of mares which have suffered from strangles and influenza.

With regard to the increased length of pregnancy which was observed in the cases of the mares injected with the Polyvalent serum;—Have we reason to believe that by the injection of a passive immuniser of the nature of Polyvalent Antistreptococcic Serum during the last stages of pregnancy we can increase the length of pregnancy? The fact seems significant and appears to me worthy of further study.

Possibly others who have used this prophylactic might be interested and may have had results similar to those which I relate.

W. WALLACE PEGGIE. M.R.C.V.S.

Biggar.

#### BACTERIAL INFECTION OF WOUNDS IN FRANCE.

The article under this heading in *The Veterinary Record* of 19th October, deals with a disease not hitherto noted in your columns, but one which has caused a good deal of speculation as to its origin. The indirect cause is a bite on the neck, but in many cases even an abrasion is absent; a soft swelling containing a liquid suddenly appears.

When I first met this condition I had no hesitation in making a bold incision at the lowest part of the swelling, which allowed the yellowish serous fluid to escape, but after finding that the fibrous tumour was usually the result I proceeded with more caution, and unless the swelling was large advised leaving it alone to see if absorption would take place. This does take place with the smaller swellings. More frequently the fluid increases until the swelling extends from four inches in front of the point of the shoulder to near the crest. Something has to be done then, and reluctantly the knife and skin are sterilised and a good incision made. I have removed in this way several pints of yellowish serum containing what I consider to be a large amount of fibrin. I always irrigate the sac with saline solution, and ensure that all fibrin

has been removed. All my cases have been with a unit in the field, and I have therefore had no opportunity of submitting any material to microscopic examination.

After incision and irrigation I plug the wound with sterilised wool. The irrigation and dressing is carried out twice daily. I have had some success in this way but the failures, as Capt. Kirk states, are many, and the tumour as described forms round the incision in a few days. I consider there is an advantage to be gained by allowing the fluid to escape, and if the tumour does form allow it to become circumscribed, and then remove it along with the overlying skin, taking  $\frac{1}{2}$  in. of the healthy skin all round. The underlying tissue has the same rough appearance as found in a case of blackleg.

Further treatment consists of keeping the surrounding skin clean and free from discharge, and application of a dry dressing of Pulv. alum and Pulv. ac. boric in equal parts.

I have had no recurrence of the tumour after operation.

The same serous abscess is often found on the hip due to a kick, but strange to say I have never observed the formation of a tumour after the removal of the fluid.

J. F. TAYLOR, Capt. A.V.C.

B.E.F., Oct. 28.

#### THE VETERINARY TRIBUNAL.

A meeting of the Veterinary Tribunal was held at 10 Red Lion Square, London, W.C. 1, on November 8th.

Present:—Mr F. W. Garnett, in the Chair; Messrs. H. Begg, J. Clarkson; Sir John M'Fadyean; Messrs. W. J. Mulvey, J. Willett.

*Minutes.* The minutes of the previous meeting were read and confirmed.

*Reports.* The CHAIRMAN read the following letter from the Ministry of National Service:—

R.3/Stud/9.

1st November, 1918.

Sir,—I am instructed by the Minister of National Service to refer to the question of the protection from Military Service and the release from the Army of Veterinary Students, and to inform you that it has been decided to protect from Military Service all Veterinary Students whose names appeared on the books of their respective colleges on the 22nd of October, 1918, so long as they continue satisfactorily to pursue their studies, but that all future students will only be protected if placed in Grade 3 on attaining military age.

With regard to Veterinary Students now serving in the Army, the Minister will be prepared to recommend to the War Office the release of such students as were in their third or fourth years of study at the date of their enlistment.

The names of third and fourth year students now serving in the Army whose release is desired should be forwarded to the Secretary (L2) at this Ministry, together with particulars of their Regimental numbers, and present stations. This Department is already in possession of the necessary particulars regarding the students who are still in civil life, and the necessary instructions for their protection will be issued, but I am to request that you will from time to time notify this department of any Grade 3 students entering the Veterinary Colleges in Great Britain subsequently to the 22nd of October, 1918. Such communications should be

addressed to the Secretary (R.3) Ministry of National Service.—I am, Sir, your obedient Servant,  
(Signed) H. N. BOYD.

It was resolved: That the matter be left in the hands of the Chairman to deal with, and that letters be written to the four Colleges for the information required by the Ministry of National Service.

The following cases were dealt with:—

MEIKLE, C. E. J., Sunderland. Age 32. Grade I. Married. N.S.R.'s application dismissed. That he be not called upon to join Volunteer Training Corps.

BUTTERS, E. L., Liverpool. Age 32. Grade II. Single. N.S.R.'s application dismissed. Temporary exemption for six months allowed, to May 9, 1919. That he be not called upon to join V.T.C.

MASSON, C., Torquay. Age 29. Grade II. Married. N.S.R.'s application dismissed. Temporary exemption for six months allowed, to May 9th, 1919. That he be not called upon to join V.T.C.

McGHEE, Thos., Tattenhall. Age 44. Grade II. Married. Man's application refused. Not to be called up till 9th December, 1918. If not offered a Commission in A.V.C., leave is granted to appeal again.

WILSON, Thomas, Nantwich. Age 32. Grade I. Single. N.S.R.'s application dismissed. That he be not called upon to join V.T.C.

ELDER, A. G., Tewkesbury. Age 47. Grade 2 B2. Married. Man's application allowed. Temporary exemption for six months, till May 9, 1919. That he be not called upon to join V.T.C.

PRINCE, F. T., Ashborne. Age 35. Category A. Married. Man's application allowed. Temporary exemption for three months, till Feb. 9, 1919. That he be not called upon to join V.T.C.

FURNESS, G. J., Alfreton. Age 50. Grade II. Married. Man's application allowed. Temporary exemption for six months, till May 9, 1919. That he be not called upon to join V.T.C.

WATSON, W. R., Thornbury. Age 35. Category A. Married. N.S.R.'s application allowed. Not to be called up till Dec. 9, 1918. If not offered a Commission in A.V.C., leave is granted to appeal again.

BISHOP, G. H., Bristol. Age 50. Married. Man's application allowed. Temporary exemption for six months, to May 9, 1919. That he be not called upon to join V.T.C.

LYDFORD, T. R., Somerset. Age 33. Grade I. Married. N.S.R.'s application allowed. Man not to be called up till Dec. 9, 1918. If not offered a Commission in A.V.C., leave is granted to appeal again. Leave to appeal to Central Tribunal refused.

WHITE, W., Birmingham. Age 34. Grade II. Married. Man's application allowed. Six months temporary exemption, till May 9, 1919. That he be not called upon to join V.T.C.

WARD, J. D. C., Hinckley. Age 42. Grade I. Married. Man's application dismissed. Not to be called up till Dec. 9, 1918. If not offered a Commission in A.V.C., leave is granted to appeal again.

HODDINOTT, D. R., Evesham. Age 30. Grade I. Married. N.S.R.'s application allowed. Man not to be called up till Dec. 9, 1918. If not offered a Commission in A.V.C., leave is granted to appeal again.

FINDLAY, A. W., Warwick. Age 43. Grade II. Married. Man's application dismissed. Not to be called up till Dec. 9, 1918. If not offered a Commission in A.V.C., leave is granted to appeal again.

SMITH, S., Horsham. Age 29. Grade III. Married. Man's application allowed. Temporary exemption granted for six months, to May 9, 1919. That he be not called upon to join V.T.C.

Hawson, F., Royston. This case was adjourned till

next meeting, as applicant was unable to attend owing to illness.

PINCHING, R. H., Horsham. Age 41. Grade II. Married. Man's appeal dismissed. Not to be called up till Dec. 9, 1918. If not offered a Commission in A.V.C., leave is granted to appeal again.

DIER, J. B., E. Grinstead. Age 51. Grade 2 B2. Married. Man's application allowed. Temporary exemption for six months, till May 9, 1919, allowed. That he be not called upon to join V.T.C.

STINSON, O., Marden. Age 32. Grade I. Married. N.S.R.'s application allowed. Not to be called up till Dec. 9, 1918. If not offered a Commission in A.V.C., leave is granted to appeal again.

ANDREW, H., London. Age 33. Grade B1. Single. N.S.R.'s application dismissed. Temporary exemption for six months allowed, till May 9, 1919. That he be not called upon to join V.T.C.

At a meeting of the Veterinary Tribunal (Scottish Panel), held at the Royal (Dick) Veterinary College, Edinburgh, on the 25th October.

Present: Mr. F. W. Garnett, in the Chair; Dr. O. C. Bradley; Messrs. H. Begg, J. Clarkson, W. J. Mulvey, J. Willett, P. Wilson, W. Wilson, W. Woods (N.S.R.), were in attendance.

Minutes. The minutes of the previous meeting were read and confirmed.

The following cases were dealt with:—

SCADE, G. M., Galston. Age 35. Grade I. Man's application dismissed. Not to be called up till Nov. 25, 1918. If not offered a commission in the A.V.C., leave is granted to appeal again.

MEIKLE, P., Strathavan. Age 37. Grade I. N.S.R.'s appeal allowed. Not to be called up until Nov. 25, 1918. If not offered a commission in the A.V.C., leave is granted to appeal again.

CAMPBELL, W. W., Girvan. Age 36. Grade I. Man's appeal allowed. Temporary exemption granted, to Feb. 1, 1919. That he be not called upon to join V.T.C.

TAYLOR, D. A., Beith. Age 36. Grade II. N.S.R.'s appeal dismissed. Temporary exemption granted to May 1, 1919. That he be not called upon to join V.T.C.

GIBSON, J., Dundee. Age 32. Grade II. N.S.R.'s appeal dismissed. Temporary exemption till May 1, 1919. That he be not called upon to join V.T.C.

FERGUSON, W. M., Dundee. Age 40. Grade I. Man's appeal allowed. Temporary exemption granted to May 1, 1919. That he be not called upon to join V.T.C.

PEGGIE, W. W., Biggar. Age 27. Grade I. N.S.R.'s appeal allowed. Not to be called up till Nov. 25, 1918. If not offered a commission in the A.V.C., leave is granted to appeal again.

MATHESON, D. C., Edinburgh. Age 37. Grade III. N.S.R. agrees to temporary exemption to May 1, 1919. That he be not called upon to join V.T.C.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

L. J. Blenkinsop, Maj.-Gen. A.V.S.	£5	0	0
James Brown, Stirling	1	1	0
A. Cornish Bowden, Beckenham	1	1	0
C. E. Perry, Bristol	1	1	0

Previously acknowledged 1077 7 11

£1086 10 11

**ARMY VETERINARY SERVICE****Extracts from London Gazette,****WAR OFFICE, WHITEHALL, Nov. 8.****REGULAR FORCES. ARMY VETERINARY CORPS.**

Capt. J. M. Richardson, M.C. (T.F.), relinquishes the actg. rank of Maj. (Oct. 21).

Nov. 11.

Temp. Qrmr. and Lt. R. H. Jameson to be Capt. under Art. 330, R. Wt. for pay and promotion (Oct. 17).

Nov. 14.

Temp. Maj T. C. Evans, M.C., Can. A.V.C., to be Dep. Asst. Dir. of Vety. Servs., and to be actg. Lt.-Col. whilst so empld. (Oct. 11).

**TERRITORIAL FORCE, ARMY VETERINARY CORPS.**

Nov. 8.

Capt. T. Eastwood relinquishes his commn. on acct. of ill-health, and is granted the hon. rank of Capt. (Oct. 7, 1916) (substituted for that which appeared in *Gaz.* of Oct. 6, 1916).

Nov. 11.

Capt. (actg. Maj.) R. W. Williams relinquishes the actg. rank of Maj. on ceasing to be employed as A.D.V.S. (Oct. 3).

**The following casualty is reported :—****DIED—Capt. A. A. Higgins.****Bull with bad feet.—Prosecution fails.**

At the Elham Petty Sessions at Seabrook, on Thursday, 7th inst., before Mr. E. Garnet Man and other magistrates, Alfred Constable, farmer, of Capel-le-Ferne, and Alfred Constable, jun., were summoned for cruelty to a bull.

Mr. G. W. Haines prosecuted on behalf of the Royal Society for the Prevention of Cruelty to Animals, and Mr. Rutley Mowll, of Dover, defended.

John Wise, 6 Park Road, Cheriton, stated that he had been an omnibus driver for nearly twenty years, and although he knew something about horses, he knew nothing about other cattle. On the 14th October he was driving a bus along the Cheriton Road, when two passengers called his attention to a bull standing against a wall opposite Mount's Nursery. The animal had a ring in the nose, and the younger defendant was endeavouring to pull it off the footpath, by means of the rope, while the elder defendant was trying to push it along. Witness proceeded to Cheriton, and on his return he saw the bull standing against a fence at Morehall. On going back to Cheriton he saw the horse lying on a heap of shingle at the end of Quedsted Road. It appeared to him to be in a distressed condition. He later saw it at Julian Road, Folkestone, lying on the roadway, and he also saw it walking as if in a distressed condition. Cross-examined : When he saw the bull at Quedsted Road, a drove of cows came along, and the bull got up and walked away with them.

Inspector Rodwell, R.S.P.C.A., stated that he saw the bull lying on a heap of stones at Cheriton. It was distressed, had its mouth wide open, and its breathing was short and sharp. There was some blood on the nose. Owing to the way in which the bull was lying he could not examine the feet, except the off fore one, which was very hot. The younger defendant was standing alongside the bull, and witness stood by from three till four

o'clock, when he then asked the man to allow the animal to remain while he rang up a veterinary surgeon and procured the float. The float was provided by the Society and no charge was made for its use, but where a person had a horse it was expected that it would be provided for drawing it. He returned in about an hour and found that the animal had been removed. He got on a bus and overtook the bull by Radnor Park. It was still distressed, but the breathing was more normal. On the arrival of the float the bull was taken to a slaughter house, and was killed on the following day. He was present, and showed the carcass to Mr. Eve, veterinary surgeon. He was also present at the post-mortem, and found that the bull had been suffering from founder, and the lobes of the lungs were somewhat discoloured. He had no hesitation in stating that the animal had been suffering, and he told the defendant not to have it removed until the float came. Cross-examined : The bull was bodily in good condition, but he could not state its weight. Under the Food Order, a bull had to go to the market to be weighed and graded.

Mr. H. B. Eve, M.R.C.V.S., stated that he saw the bull lying on the pavement outside Radnor Park. It was "blowing," which was quite a common complaint, and it was suffering from founder of the feet and from collapse. On the following day he saw the carcass at the slaughter-house. It was an extremely good carcass for war time. He found slight congestion of the lungs. The distressed breathing he had noticed had only been caused by exertion. Cross-examined : He was quite satisfied that the condition of the bull was due to exhaustion, and it was quite natural that when a drove of cows came along from the market that the animal should rise and walk with them. It was in splendid condition.

When cows and horse were really tired out they had different ways of resting. A cow would lie down. This animal was a good bred shorthorned bull, about a year and ten months or two years old. There was no deformity about the feet, but it was just suffering from a temporary attack of founder. By the Chairman : In his opinion the bull was all right when it left the farm. It was a stall-fed bull, kept for stud purposes, and the journey from Capel to Cheriton was too much for it. It was suffering just from a temporary attack of fever in the feet.

Mr. Mowll said the bull, which was kept for stud purposes, was travelled carefully as far as the Blackbull Road Schools at Folkestone, where the children seemed to have first of all excited it. This animal was "a gentleman which had been accustomed to a sedentary life," and was not accustomed to running on hard roads. Mr. Constable, sen., had gone on to the market where the bull was to be graded, and the graders, one of whom was Mr. Hann, of Folkestone, a well-known farmer and butcher, suggested that as some other animals were going towards Folkestone, possibly the bull would get up from where it was seen lying by the Inspector and follow them. That was exactly what did happen. The weighers and graders under the Food and Control Order had the animal weighed and graded. The weight was 11 cwt., and it was placed in category 2, the Government price being £42—not at all a bad record for an animal said to have been badly used. There was no cruelty, and no reasonable being could think that the defendants could have prevented the bull from rising and following the passing drove of cattle.

The case was dismissed.—*Folkestone Herald.*

**Personal.**

**CAREY—ROBINSON.** On the 31st Oct., at the English Church, Havre, Peter Dudley Carey, Major A.V.C., only son of the late Peter Francis Carey and Mrs. Carey, Guernsey, to Dorothy Madelaine, youngest child of the late J. H. Robinson and Mrs. Robinson, of 14 Park Road, Richmond, Surrey.

### Prevention of Anthrax.

The Departmental Committee appointed in 1913 to inquire into precautions for preventing danger of infection from anthrax in the manipulation of wool, goat hair, and camel hair, have issued their report as a White Paper. One of their most important recommendations is the abandonment of the attempt to control anthrax by regulations as being totally inadequate to cope with the danger. They state that the simplest, cheapest, and most effective method of preventing anthrax in the wool trade is by disinfection of wool and hair abroad. It is recommended that the British Government should establish the disinfection authority, and should then take steps to obtain the co-operation of the Governments of all organised countries.

### Action of Permanganate on Morphine.

Morphine is rapidly oxidised by potassium permanganate. It has been found that when a solution of 0.5 gm. of permanganate is added to a solution of 1 gm. of morphine hydrochloride, instantaneous reaction takes place, the colour of the liquid changing to mahogany-brown, while manganese dioxide is precipitated, nearly all the morphine being converted into pseudomorphine. With increasing quantities of the permanganate, oxidation continues, the colour of the liquid gradually changing to straw-yellow, while the newly-formed pseudomorphine disappears and alkali oxalate is found in solution. The reaction is expressed thus:— $2C_{17}H_{19}NO_3 + O = (C_{17}H_{18}NO_3)_2 + H_2O$ . The product is oxydi-

morphine (or pseudomorphine), which is much less active as a narcotic than is morphine. Some of the pharmacologists simply say that "the morphine is oxidised and is rendered inert."—*Pharm. Jnl.*

### Eau de Javelle for disinfecting wounds.

It is claimed that a dilution of 15 gm. of commercial Eau de Javelle to one litre with water furnishes a liquid disinfectant which is superior to Dakin's solution as a surgical disinfectant irrigant. It is worthy of more general use in the treatment of wounds, being less irritant and more actively bactericidal than Dakin's fluid. The authors consider the latter to be too strong in sodium hypochlorite, rendering its action distinctly irritating. The commercial Eau de Javelle used in their experiments contained 2.7163 per cent. of available chlorine and 2.37 per cent. of soda (*sic*). [In normal times, Eau de Javelle is a solution of chlorinated *potash* containing 3 per cent. of available chlorine.]—Cazon and Krongold (*Comptes rend.*, 1917, 165, 569, *ex Pharm. Jnl.*).

### OBITUARY.

ARTHUR AKIN HIGGINS, Greenhill, Harrow,  
T./Capt. A.V.C. Graduated, Edin: May, 1910.

PAGE BULL.—Killed in action, on Oct. 30, Ronald Page Bull, 2nd Lieut. Northamptonshire Regt., the dearly loved and only son of Mr. and Mrs. R. Page Bull, of Deddington, Oxford; aged 19½ years.

VOL. XXXI.

## THE RETURN TO CIVIL LIFE.

Recent events seem to indicate that we may soon expect the beginning of demobilisation, and the gradual return to civil life of the majority of the thousand odd members of the profession who have been away on active service. It will be no light matter to arrange the resettlement of these members in civil life. How many of them will have practices to which to return, and how many will have no practice to return to? It may be said that practically none of the young men who have graduated since June, 1914, have seen much of civil practice. Some method of introducing them to suitable posts, as and when demobilised, will need to be devised; and some means provided to help those members who having left a practice find on their return it has gone. The Council of the Royal College of Veterinary Surgeons has its representative on the Committee set up by the Ministry of Labour to deal with the resettlement of officers, and it may be hoped that a workable scheme will be evolved in due time.

But cut and dried schemes are one thing, and the carrying out of them another. Practically everything will depend on the sympathetic co-operation of those members who have not been called upon to leave their practices. In many cases friendly arrangements have been entered into for the practice of a member on active service to be carried on by his neighbours until his return. These members will shortly be coming home, and the reckoning will call for much forbearance and unselfishness on both sides. Generous treatment is at least due to the man who has had to leave all, and don khaki. No doubt it will be difficult in some cases to hand over clients when a man has been away for a length of time. Some clients will not want to go back to their former veterinary surgeon, and obviously cannot be compelled to do so. We have confidence that the majority of those at home who have been acting for an absent member will crown the good work they have been doing for so long by intimating to all old clients that they *must* now go back to the returning member. Some, unfortunately, will be returning in far poorer health than when they left. These especially deserve every man's sympathy and help. It is to be hoped that the profession at home will think of these things, and be generous.

## \* BACILLARY NECROSIS IN THE HORSE.

By Capt. GEORGE HOWIE, Remount Depot,  
Aurangabad, Deccan.

Mr. President and Gentlemen,—My father, in one of his letters, asked me if I could write a paper for one of your meetings as I might have encountered cases in India which might be of interest to the members.

As very little has been written concerning the disease commonly called Contagious Necrosis, I hope it may interest you to hear about my experience with this troublesome disease.

7th June, 1918.

**Bacteriology.** Not being a bacteriologist, and having very few facilities for the thorough examination of smears, I am not in a position to say much regarding the causal organisms giving rise to the disease, but judging from one or two experiments I made the disease is caused by *Bacillus Necrophora*. I have found *B. Necrophora* on taking smears from lesions and examining them microscopically. I also succeeded in demonstrating the organism by inoculating a hare subcutaneously with a small quantity of the discharge obtained from one of my cases. The discharge was mixed with about an equal quantity of normal saline and injected subcutaneously in the abdominal region of a young hare. Five days after the inoculation the hare died. There were no local lesions; but lesions were found in the liver, which, on examination by the Imperial Bacteriologist, Muktesar, proved to be *B. Necrophora*.

*B. Necrophora* is undoubtedly the chief causal organism, though other agents assist in the progress of the disease, such as *Streptococci* and *Staphylococci*. Wet standings and insanitary conditions are the chief predisposing causes; this is evidenced by the fact that the disease is worst in the monsoon season.

I have noticed that horses' skins become extremely non-resistant to disease in the monsoon season, the slightest wound being very difficult to heal.

**Symptoms.** These are extremely varied, varying with the extent and position of the wound, and probably also with the virulence of the causal organism.

The commonest symptoms are: Pain, affected parts hot, extremely sensitive to palpation, and

\* Read at the meeting of the North of Scotland V.M.S., Aberdeen, Aug. 29. (V.R., Nov. 2, p. 148).

swollen; if a wound be present—and there is almost always a wound—it is unhealthy in appearance and usually shows a discharge of pus. The temperature is usually elevated, I have seen it as high as 107°; pulse and respiration accelerated; animal off his feed; and the mucous membrane injected. If the infected wound be near the foot the animal is always lame.

During 1917, from about the end of May to the end of September, I treated, I should think, from 200 to 300 horses suffering from necrosis. To assist in the treatment I divided the cases provisionally into three classes according to the severity of the infection, this division also helps in describing the different symptoms encountered.

Class I (I called) Simple Necrosis; Class II, Suppurating and Sloughing Necrosis; Class III, Suppuration without sloughing.

*Simple necrosis.* These cases were usually quite easily dealt with, and were discharged in a few days. The seat of the disease was usually the bulbs of the heels, and mostly on the hind feet.

There was usually no actual wound—only a slight abrasion. The part was denuded of hair, reddish-yellow in colour, and a yellowish glairy pus could be seen oozing through the surface of the abrasion.

The horse usually showed slight symptoms of lameness but very little pain on palpation, and after applying suitable dressings and keeping the parts clean for a few days, the abrasion soon dried up. (Photo. 1).

*Suppurating and sloughing necrosis.* This is a much more severe form of the disease. A horse is brought into hospital suffering from a rope gall, over-reach, or ordinary wound which may be situated anywhere on the body, though the legs are most often affected, as they are more likely to come into contact with the organism.

The wound when examined is found to be a raw unhealthy sore, discharging an evil-smelling sulphur-yellow pus—a sinus is very rarely found, the pus appears simply to ooze through the surface of the granulations which usually cover the surface of the wound. If the infected wound be in the vicinity of the foot the animal is invariably lame; the leg may be hot and painful and is usually swollen.

If the wounds have been neglected for some time before receiving proper attention the animal may show very serious symptoms. It is usually "dead lame," the wounds are covered by unhealthy purple granulations, discharging an evil-smelling pus tinged with blood. If the wounds are in the region of the coronary band the bands are swollen, cedematous, and yellowish in colour, there is also very often separation between the hoof and coronary band. The leg is hot, extremely painful, the animal is dull, "off feed," and the temperature may be anything up to 107°, though it is usually not much above 105°; pulse up to 60; mucous membranes injected. In one case symptoms of pleurisy were present. If the progress of the disease is not arrested the animal becomes rapidly worse, the sores enlarge, and the discharge of pus increases.

When a slough is to take place a line of demarcation is seen near the margin of the wound, usually distinguishable by being slightly darker in colour than the surrounding tissues. The sloughing process is hastened as much as possible and the slough when ready is removed surgically.

In most cases when the slough took place the severity of the symptoms abated, the flow of pus decreased, and healing was fairly rapid. (Photos. 2, 3).

In two cases, when the wound was in the vicinity of the hoof, sloughing of the hoof had commenced before sloughing of the wound took place, and the animals had to be destroyed.

*Suppuration without sloughing.* In most cases the primary symptoms were much the same as those described in Class II, but one or two cases, although undoubtedly "Necrosis," differed from other cases. The following is the history of one unusual case,

The horse was admitted to hospital on October 16th, 1917, and was found to be lame near hind. No sign of the slightest wound could be seen anywhere, in the region of the foot only a slight tenderness was shown below and anterior to the fetlock joint.

On the following day there was still no sign of anything beyond a slight swelling on the above mentioned spot.

During the night of the 18th, what seemed to be a deep abscess had burst below the fetlock and a copious discharge of the usual sulphur-coloured pus was coming from the opening.

On the following day two more openings had appeared, but after applying dressings for four days the discharge ceased and the wounds commenced to heal.

Six days later, on the 28th, a fresh lesion appeared at the back of the fetlock joint, and the following day two more lesions on the pastern, posterior to the original lesion. (Photo. 4).

The discharge had again ceased on the 2nd November, and the horse was fit for discharge on the 12th. The case had all the aspects of "Necrosis," but no sloughing took place, and the absence of a wound on admission makes it unusual. I give the case in full to show that it is apparently not necessary for a wound to be present to enable invasion by the causal organism to take place.

Luckily I encountered only a very few cases in this class—about 20 in all; four of these had to be destroyed as the progress of the disease was very rapid.

The serious cases were mostly due to neglect before admission, but one case in particular was not due to this cause, and I think it is worthy of mention to show the rapid progress of the disease.

This case was admitted suffering from a wound above the coronary band on the outside of the near fore. The wound was bluish-grey in colour, not painful, with the usual moist appearance due to the oozing out of the pus. No very marked lameness was present.

Next day the lesion had enlarged, discharge of pus had increased, and the bluish granulations had

assumed a dark chocolate-coloured appearance. The region near the coronary band was swollen and painful; the coronary band itself was bright yellow, and a slight separation was visible between it and the hoof.

On the third day the lesion had enlarged and was more unhealthy in appearance, and the odour of the discharge was almost overpowering; also the hoof had commenced to slough. The temperature was 106°, pulse and respiration accelerated, animal dull, off feed, and in great pain. The leg was swollen to almost three times its size as far as the elbow.

The animal had to be shot on the fourth day, as the hoof had almost sloughed off, and all the tissues above the hoof were diseased. The horse was almost mad with pain before he was destroyed. All these symptoms occurred in four days, and the progress of the disease could not be arrested although dressings were applied every two or three hours.

I would like to discuss one more case which showed unusual symptoms, because I have photograph of it. This case was admitted on the 7th October suffering from a necrotic wound on the off hind pastern, evidently caused by a shackle. The wound had been neglected, and in consequence the symptoms were fairly severe; temperature raised, leg swollen and painful, copious flow of pus, etc.

After cleansing the wound, poultices were applied continuously up to 13th October, when "Eusol" and "Eupad" were commenced. The discharge ceased on the 16th, and no slough took place. The wound healed rapidly and the animal appeared practically fit to be discharged on the 22nd Oct.

During the night of the 24th the leg commenced to swell, and in the morning it looked as it were a case of lymphangitis. The animal was very lame and the leg hot and painful, but no pain was shown on palpation of the lymph glands.

An attempt was made to foment the leg, but being a remount he would not stand still, so the only alternative was to apply flannel bandages round the leg and keep them moist with hot water.

The leg had not decreased in size next day, and numerous small sores, about the size of split peas, were visible on the inner surface of the leg extending from the hock almost to the fetlock; discharging a thin serous fluid which coagulated on the leg.

A wound had also appeared on the anterior surface of the leg just above the fetlock. (Photo. 5). The swelling on the leg had extended also to the sheath and along the abdomen. (Photo. 6). The original wound had also "broken out" again, so I concluded that all these symptoms were due to necrosis. Poultices were again applied, and fomentations continued.

The poultices were discontinued on the 28th, the leg had decreased in size and the eruption on the inner surface of the leg had disappeared, so too had the oedema of the abdomen and prepuce. The patient was discharged a week later.

**Diagnosis.** The diagnosis is always quite simple, except in very unusual cases, such as I

have mentioned. Once one has seen a necrotic wound and the sulphur-coloured pus oozing through the surface of the unhealthy granulations, it could not be mistaken for anything else. A smear taken from the wound almost always shows the bacillus—I used Giemsa's Stain.

The prognosis is favourable except in very severe cases, provided dressing is regularly carried out and strict cleanliness of the affected parts be observed. If the case has been neglected for some time several sequelæ may result. These I will mention later.

**Treatment.** After spending about a month in trying to find a successful method of treatment, I hit upon a very simple, and what I found to be very successful treatment.

Previous to this treatment I tried almost everything in the Pharmacopœia; both externally and internally. Amongst others, I tried soaking the part affected, if near the foot, with solutions of Hydrarg. perchlor. of varying strengths, Salt solution, Eusol, Pot. permang., Iodine, Carbolic acid, Zinc chloride, Pot. permang. crystals, and bran poultices. I gave Arsenic, Pot. Iod., Hyd. Biniod. Rub., and Quinine internally, I also tried Eusol and weak solutions of Carbolic acid intravenously, but got no marked results.

I at last tried Eusol and Eupad treatment, and got good results. It struck me that if Eusol was a good dressing for infected wounds, so might the sediment left over after the Eusol was filtered off—this sediment I called Eupad.

The dressing is easily made and inexpensive—which is a big item in these times. I had usually two Winchester quarts of the solution made at the time. For this I required 3 oz. Boric acid and 3 oz. Chloride of lime, which was mixed together, put into the Winchester and water added to fill the bottles—the mixture well shaken and left overnight. In the morning it was filtered and the sediment collected.

The different classes were treated somewhat differently.

**Treatment for Class I.** On admission the wounds were cleansed thoroughly with soap and water, the wounds being scrubbed with an ordinary nail brush, using as little water as possible. The hair round the wound was then clipped and the wound dried—it was then bathed with Eusol, dried, and smeared with Eupad and a pad of tow and bandage applied.

The wounds usually dried up in 3 or 4 days.

**Treatment of Class II.** After cleansing the wounds with soap, water, and a brush, a linseed poultice was applied if any sign of sloughing was visible. The poultices were applied in elongated bags and renewed every three or four hours.

As soon as a line of demarcation showed I removed the slough surgically, washed the wound with Eusol and applied Eupad, and dry pads and bandages.

The discharge of pus soon ceased after removal of the slough, and the Eupad promoted rapid granulation. As soon as the wound had granulated sufficiently the Eupad was discontinued, the part being kept clean with moist Eusol pads—Boric acid was the only dressing applied. After the

slough had separated the wound invariably healed uninterruptedly.

*Treatment of Class III.* This class being the most severe was the most difficult to treat. There was usually a copious discharge of pus being evacuated from several small openings.

After the part had been cleansed, poultices were applied to promote sloughing if possible, and if not, they served to alleviate the pain and "draw" the pus. The poultices were renewed about every two hours and the wound syringed out with Eusol.

As soon as the discharge of pus had decreased the poultices were discontinued, and Eusol and Eupad applied three times a day, and the wounds protected with hot dry pads and bandages. I very seldom gave medicine internally other than a dose of physic, and Mag. sulph. and Pot. nit. in the drinking water.

The success I obtained from this treatment I put down to the use of non-irritant dressings and keeping the parts affected as dry as possible. Irritant dressings and moisture seem only to aggravate the condition.

*Post-mortem.* Most of the cases examined were very severe (Class III), and in every case the wounds were near the foot.

When the skin was removed the tissues underneath were of a dark chocolate colour infiltrated with pus. In some cases the tissues were gangrenous, as I was able to remove the diseased portions with a teaspoon right into the bone—in one case I was able to scoop out the soft tissue of the foot like an egg.

I found no lesions in the abdominal organs. In old-standing cases there are usually large masses of fibrous thickening round the wound.

*Sequelæ.* The most common sequel to the disease is permanent thickening of the leg, and very often a fibrous thickening in the neighbourhood of the lesion. (Photo. 8).

Another fairly common sequel, especially in cases which have been neglected, is Quittor.

Arthritis is also somewhat common if the wounds be near a joint—most commonly the fetlock joint.

I had also one case where part of the extensor tendons sloughed. I hoped that a small part of the tendon had remained, and succeeded in getting the wound to heal, but the animal was unable to extend his leg, so it had to be destroyed. I forward a photo. of the case, also a photo. of the tendon on post-mortem. The flattened part is fibrous tissue uniting the two ends of the tendon, and is adherent to the bone. (Photo. 7).

Meerut, India, 1917.

#### REFERENCE TO PLATE.

- 1 Simple necrosis: lesions on heels.
- 2 Surface wound, partly healed.
- 3 Large slough on point of hip.
- 4 Suppuration—no wound. Fresh lesions ten days later.
- 5 Fresh lesion, after a previous wound on pastern had healed.
- 6 Same case; swelling showing on sheath and abdomen.
- 7 Fibrous tissue, replacing portion of extensor tendons destroyed by sloughing.
- 8 A permanent thickening.

#### DISCUSSION.

Mr. BROWN, President: We have listened to a very excellent and interesting paper. This bacillary necrosis is commoner in this country than we are aware of. For instance: Foul of the foot in cattle, Foot rot in sheep, so-called Calf diphtheria, and Necrosis of the coronet in horses in winter time are all forms of Bacillary necrosis. I am sure all of you have seen and treated these cases.

Mr. HEPBURN: I have listened to Capt. Howie's paper with very great interest. We meet with bacillary necrosis almost every day, though, perhaps, we do not recognise it. We have it in severe cases of cracked heels in horses. My treatment is on the same lines as Capt. Howie's. The secret is to keep the parts as dry as possible, as moisture is very harmful. I had the same kind of cases to deal with in the South African campaign. I have tried Eusol in fistulous withers but with no good results. I will try Capt. Howie's treatment and methods in future.

Mr. CUMMING: I beg leave to offer my congratulations to Capt. Howie for his very instructive paper. The photographs are also excellent. I haven't seen much of the disease in country practice, though it is common in towns. I approve of dry dressings for cracked heels and such like sores.

Mr. BEATTIE: I have to thank Capt. Howie for his clever and literary paper. The disease in India seems to be confined to the extremities. I have two or three cases of intractable sores on the jaws of horses. I wonder if it is the same disease? I shall try the Eusol and Eupad treatment.

Mr. DRENNAN: I would like to add my thanks to Capt. Howie for his very instructive paper. The disease is common here in winter as a result of tramps, etc. Dry antiseptic treatment I find is best. Tubbing is the worst possible form of treatment.

Mr. ANDERSON: I wish simply to thank Capt. Howie for his paper. I have got quite a lot of useful information out of it.

Mr. BROWN: Capt. Howie is to be congratulated on his exceedingly lucid and well written paper, and on his original and successful treatment of such a stubborn disease. The principle of the treatment is dry, non-irritant application.

On behalf of the Society, I would ask his father to convey to Capt. Howie the thanks and appreciation of the members; and we all hope he will soon be back amongst us again.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### CARDIAC DISEASES IN ARMY HORSES.

The severe labours which horses undergo in this war, coupled with the length of the war, in many cases affect the heart; and therefore cardiac lesions, which were rather rare at the beginning of the war, are now fairly frequent in the horses of all the armies. It is true that even at the beginning of the campaign, especially during advances and movements from one sector of the front to another by long and rapid marches, acute lesions of the myocardium were not lacking, causing speedy death, or necessitating the "casting" of the animals. At the beginning of the war this casting was not difficult, for horses were then fairly plentiful. Now, in view of the scarcity of horses, it is

BACILLARY NECROSIS. To illustrate paper by Capt. GEORGE HOWIE, A.V.C.

necessary to attempt the treatment of cardiac diseases. This, by means of accurate examination, which permits a precise diagnosis, and a suitable treatment, is not impossible in a good number of cases.

Severe work, scanty and bad food, and chronic diseases of other organs, first cause cardiac debility. The horses appear fatigued and exhausted; they have little appetite; any every slight effort causes profuse sweats. The pulse is weak, soft, and often irregular; the number of pulse-beats is 50, 60, or much more. The impulse of the heart is distinct at first; but, with the prolongation of the cardiac debility, it becomes weak in consequence of a degeneration of the myocardium. The cardiac sounds are at first clear but weak.

This form of cardiac debility is often observed in horses which have participated in long marches or in fatiguing work at munition transport during periods of military action. It is not rarely accompanied by moderate swelling of the limbs.

The affections which determine an organic lesion of the myocardium are as follows:—

*Acute myocarditis* occurs in the course of severe infectious diseases, the result of which depends upon the resistance of the heart. In this affection the pulse is small, scarcely perceptible, and arrhythmic. It counts up to 100 per minute, and more. The cardiac sounds are weak, with the first sound dull and indistinct. The mucous membranes are reddened; and high fever, debility, and exhaustion are present.

*Acute cardiac hypertrophy* is often the consequence of overwork. In this affection the impulse of the heart is palpitating. The pulse is full and strong. Percussion reveals an extensive dulness. The pulse reaches 60 to 80 per minute, and is generally regular. The cardiac sounds are clear. Any slight effort causes a profuse sweat, great weakness, and a tumultuous throbbing of the heart.

Defect of the Bicuspid is the most common *valvular affection of the heart*. In this case the most important diagnostic symptom is an extensive systolic murmur, usually a blowing sound, which is heard at its maximum in the fifth intercostal space. This systolic murmur is usually also perceptible in the great arteries (carotid, etc.) The second cardiac sound is clear. The pulse is frequent and weak. When these horses are made to move the systolic murmur increases, and dyspnea occurs in consequence of a venous hyperæmia in the lungs.

*Insufficiency of the aortic valve* may also be encountered, though more rarely. The principal symptom of this is a diastolic murmur which is perceived at the fifth left intercostal space. The pulse is full, strong, and bounding; This character is due to the fact that the heart throws a great quantity of blood into the aorta, a part of which regurgitates in consequence of the imperfect closure of the semi-lunar valves.

The treatment of cardiac diseases generally gives good results, provided that rest and good feeding are not lacking. The best remedy is *Pulv. digitalis*

*ol.*, which is given in liquid in doses of from 6 to 8 grammes. This regulates the cardiac function and augments the arterial pressure. Digitalen and digalen give less good results, and also have the drawback of being more costly.—(*La Clinica Veterinaria*). W. R. C.

#### Inoculating Cows against Contagious Abortion.

The following is from a note on the Report for 1917 of the Munster Dairy School and Agricultural Institute in *The Farmers' Gazette*.

"We wish more particularly to refer to the further account given of the scheme for inoculating cows as a preventive measure against contagious abortion. This work was first started in 1916, when Mr. J. F. Healy, M.R.C.V.S., was engaged by the Institute to test the value of the inoculation method which had already been found of great use in some parts of England. In that year 140 cattle were inoculated (free of any cost to the owners), and the results, which were quite satisfactory, have already been published. It was decided to continue the work in 1917, but it was arranged that only herds belonging to members of the Institute should be treated. One herd of 14 animals was sold and dispersed after inoculation, five other cows were sold subsequently and lost sight of, and one died. Of the remainder only 11 aborted, and two were barren, giving 7.78 per cent. of the total number left at the end of the experiment which did not produce a live calf.

*Cows inoculated.	Calved right.	Remarks.
10	4	4 cows sold, 2 barren.
15	13	1 aborted, 1 was sold owing to having a bad dug
12	11	1 aborted. The owner thinks this was the result of an accident as it occurred two days after jumping a fence.
32	29	2 cows aborted, 1 died.
20	18	2 aborted.
15	13	2 aborted.
25	24	1 aborted.
19	16	2 aborted within two months of their time. 1 also that was not inoculated.
14	14	2 cows not inoculated aborted.
14	—	Herd sold by order of Govt.
8	—	Doing well.
3	—	Doing well.

\* All these animals had previously aborted.

**BAILLIÈRE'S ATLAS OF THE HORSE, ITS ANATOMY AND PHYSIOLOGY.** By O. CHARNOCK BRADLEY, M.D., D.S.C., M.R.C.V.S., Principal of the Royal (Dick) Veterinary College, Edinburgh, and THOMAS G. BROWNE, M.R.C.V.S., Professor of Anatomy, Royal Veterinary College, Dublin. With original plates by GEORGE DUPUY, M.D. Size 9½ by 17½. Pp. 38. Five coloured and eight plain plates. Price 7/6 net. (Baillière, Tindall, & Cox, 8 Henrietta St., Covent Garden, London, W.C.)

The "Anatomical and Physiological Atlas" is much more anatomical than physiological, only a little physiology is included in it. It naturally divides into two parts, text and notes; and the former of these may again be subdivided into two. After a short introductory section, we have a survey of the anatomy and physiology of the horse. This comprises rather more than nineteen three-column pages, and may be summarily described as containing about as much information, conveyed with admirable lucidity, as it would be possible to compress into so small a space. Except that the section upon the lymphatic system, which is very short, and differs from most of the work in containing rather more physiology than anatomy, might advantageously have been lengthened a little to convey more detailed information of the location of the glands, there is little scope for criticism. The whole of the remaining portion of the text is devoted to a description of the plates. This is very well and carefully done, and is more than a mere description of plates; for not a few additional anatomical details are interspersed. The plates themselves are excellent, both in their selection and execution. The thirteen plates contain no less than 119 figures, a dozen of which are of obstetric presentations; and altogether they form a most useful collection.

The book is the best one of its class we have seen, and will be useful to very varied sections of readers. Its utility to the veterinary student for strictly examination purposes is limited; for the text, as the mere enumeration of its pages shows, does not contain nearly sufficient detail for either the first or the second professional examination. The plates will be more useful to the student for reference upon special points and comparison with other works; and here the practitioner also may occasionally find the book useful. It will be of greater utility to the first-year student desiring a good general idea of equine anatomy before entering upon its details; and for this purpose it is probably the best book available. Also, it will be valuable to many horsemen who wish to know something of the subject; for there is nothing in it that a moderately educated reader cannot grasp with a little trouble. Altogether the work is of genuine utility, and well worth its small cost.

W. R. C.

**COMMON DISEASES OF PIGS AND THEIR DIAGNOSIS, INCLUDING SWINE FEVER AND ITS TREATMENT WITH SERUM.** By ERNEST PEACEY, F.R.C.V.S. Crown 8vo. Pp. viii. +114. Price 8/6 net. (Baillière, Tindall & Cox, 8 Henrietta Street, Covent Garden, London, 1918).

In the preface to this little book the author says: "The following notes are the outcome of more than twenty years practical experience, and I have reason to hope that they may help the veterinary practitioner to arrive at a solution of the many problems which confront him in the exercise of his profession, and that they may be of equal assistance to the veterinary student and the stockowner." Two or three sentences later he remarks, "My aim has been to present a condensed account of the various diseases of swine as encountered in ordinary practice." These two extracts, with the title and number of pages, give a fair idea of the nature and scope of the book. It consists of a series

of short (in many cases very short) sections upon the numerous subjects embraced by the title, with additional sections upon the feeding and general management of pigs, dentition, and some statistics. Like several other writers, the author strongly condemns the unreasonable and mischievous practice of feeding stale swill to pigs. All the commoner diseases of pigs, including those which are scheduled, are dealt with, chiefly as to their symptomatology and post-mortem appearances, with a view to differential diagnosis. Therapeutics are seldom entered upon; though there is a short and quite non-technical section upon the serum treatment for swine fever.

So many subjects are included in so small a space that the work is inevitably very superficial in character; all the more so from the fact that it has been written for lay as well as for professional readers. There is little in it which a layman cannot readily grasp; there is a good deal, on the other hand, which need not have been inserted had the book been written for veterinarians alone. Still, the author has managed to compress a good deal of information into his small space, especially as regards symptoms and post-mortem lesions; and so little has yet been written upon the differential diagnosis of porcine diseases that probably many practitioners will find the book helpful. A larger and more detailed work upon the same subject, written for professional readers and including therapeutics, is one of the needs of the times; but for the present, this little volume is likely to do useful service.

**TERMINOLOGY AND DIAGNOSIS.***To the Editor, "The Veterinary Record."*

Dear Sir,—That knowledge of essential causes should be clearly outdistanced by terminology is, of course, one of the things to be regarded simply as inevitable: for pathology had appeared all too late, and the lead held from the first by arbitrary differentiation it has ever since maintained. Thus, various clinical manifestations having, for all that is known to the contrary, a common cause have come to be differentiated, the one from the other, and each regarded as the expression of a separate and wholly different specific cause.

Take, for instance, the existing classification of infectious respiratory diseases, more particularly "Strangles," and what is referred to as "Catarrhal influenza"—a differentiation, needless to say, that is not approved by anything like irrefutable bacteriological evidence. Nor does it appear admissible even on the clinical evidence whereon it is supposed to be based. Hence the insuperable difficulty ever besetting the matter of segregation where in an outbreak of infectious respiratory disease characterised from the first by catarrhal symptoms, a variable proportion, say 75% more or less, of the affected cases in a stable show symptoms which, according to the tenets of differential diagnosis should be referred to Catarrhal influenza, whereas the less proportion show symptoms which indicate unmistakably "Strangles" infection. As regards differential diagnosis and segregation under these circumstances, the fact is that in no other direction may clinical observation be more inevitably and completely confounded—that is to say, if the clinical differences upon which this distinction is based should be regarded seriously.

That these differences can hardly be so regarded there are, of course, those who have for long enough been persuaded. And evidence is accumulating which goes to show that the unquestioning acceptance of the differentiation in question is by no means generally admitted. Of this evidence not the least gratifying part is a decidedly less emphatic enunciation of this distinction in some of the latest text-book expositions on the subject.

In view of all the circumstances wherein this divergence of symptoms is known to appear, the idea that "Strangles" and Catarrhal Influenza are fundamentally different necessarily pre-supposes the simultaneous appearance of two separate and different infections, explicable—if at all—only in terms of coincidence. But the very fact of the known frequency of the occurrence of this divergence of symptoms will hardly admit of this explanation. Nor is it admissible in view of what knowledge there is of the order of succession of different bacterial invasions; far less by what is known to occur not only in the stables, but under circumstances of complete isolation and of infection under natural conditions—as in the case of young, unbroken

horses in the open. Even under these circumstances it is to be observed the divergence of clinical symptoms upon which this differentiation has been upheld.

How very misleading so doubtful a basis of differentiation may well be, the history of bacteriological research proves conclusively; just as it proves that these differences of clinical manifestations, so far from being necessarily related to different causes may be in reality but the varied clinical expression of different degrees of virulence of the infective agent on the one hand, and of varying degrees of receptivity on the other; and thus it is that the pathway of bacteriological advance is marked more perhaps by the effacement of arbitrary differentiations based on apparently divergent clinical manifestations, than by anything else.

What further abridgement in terminology is thus destined to undergo is a question of speculative interest. As in the past so, doubtless, in the future, by slow, yet by inevitable degrees, bacteriological research it may be hoped will reveal, among other things, what correspondence there really is between nomenclature of respiratory diseases and the relevancy of its application.

Yours faithfully,

L. McLAREN, M.R.C.V.S.

#### A CORRECTION.

Mr. G. A. Banham, Mr. H. J. Dawes, and Mr. S. H. Slocock were present at the meeting of the Veterinary Tribunal on Nov. 8. Their names did not appear in list of members published last week.

#### OBITUARY.

DAVID COOPER, M.R.C.V.S., Ribbleson, Lancs.

Graduated, Edin: April, 1873.

Mr. Cooper died 15th November, aged 70 years.

ALFRED HOLBURN, M.R.C.V.S., Congleton, Cheshire.

Edin: May, 1894.

Mr. Holburn's death occurred suddenly on Saturday, 16th inst.

GEORGE MURRELL, "Existing Practitioner," retired, Ashford, Kent.

Death took place 1st November, at the age of 86.

LLOYD.—At Oswestry, Shropshire, on November 11, Hilda, dearly-loved elder daughter of Mr. and Mrs. J. S. Lloyd, Brook Lodge, Fulwood, Sheffield.

#### The late Mr. Searby.

A correspondent sends us the following notes:—

Mr. BERNARD A. SEARBY, M.R.C.V.S., of Ramsey, Huntingdon, whose death occurred on October 29th, at the early age of 34, from pneumonia following influenza, commenced to practice in this district a few years ago, and speedily made headway in the county. His wide professional knowledge coupled with a genial disposition gained him many friends, and the news of his death will be received with general regret, not only by his clients and professional colleagues, but by a wide circle of acquaintances. Much sympathy is expressed for his wife and children.

VOL. XXXI.

## METHODS OF WOUND TREATMENT.

The article by Mr. F. T. Harvey upon "B.I.P.P." treatment of wounds, which appeared recently, will interest many practitioners. The treatment, so far, seems to have been little used in veterinary surgery, in civil practice at least, but it deserves an extended trial—for two reasons. One is the notable success which the treatment has achieved in human surgery; the other, and a stronger one, is its peculiar adaptability for general veterinary practice.

The importance of adaptability to veterinary conditions is well shown in the comparison between the three methods of wound treatment now most in vogue amongst human surgeons, with which Mr. Harvey concludes his article. Carrel's treatment has given wonderful results in human surgery; but those who are acquainted with its complicated details will admit that its use in veterinary work will always be subject to very considerable limitations. Something like this might also be said, though perhaps not quite so strongly, of Wright's hypertonic wound treatment. Both these methods may prove very valuable in our work—under suitable conditions; but there are many veterinary cases, the great majority in some practices, in which they would probably be much less efficacious than older antiseptic methods which have been known for decades.

For wound treatment in every-day veterinary practice, two of the chief desiderata are simplicity and the minimum of responsibility upon lay attendants. Carrel's and Wright's methods are far from meeting either of these requirements; but the case is different with the B.I.P.P. treatment. This latter certainly demands scrupulous care at the time of its application; but that can be given by the clinician himself, and nothing need be left for laymen to perform in the intervals between professional visits. General practitioners, who know too well what lay treatment of wounds very often is, even after careful veterinary instruction, will appreciate the value of this qualification.

Even though this B.I.P.P. method, like other procedures for wound treatment, may lose its present favour amongst surgeons working under good conditions, it may yet have a considerable future in every-day veterinary work. Very often, in general veterinary practice, the question is not What is the ideal treatment? but What treatment can be most effectively carried out under these conditions? This is the consideration which renders such treatments as the B.I.P.P. especially worthy of veterinary attention. It is not surprising that Mr. Harvey has had good results from it; and he has done a useful service by communicating them to the profession.

## THE TREATMENT OF EQUINE MANGE WITH NICOTINE.

Querruan published an article upon this subject in the *Revue generale de Médecine Vétérinaire* for 1917. The following are his general lines of treatment. He forbids all local or general clipping. He treats all mange horses in their units, even in cases where the disease is dispersed or generalised; the only mange patients he sends to the dépôts are those which are enfeebled. His treatment is the application of lotions containing standardised extract of nicotine, the formula being extract of nicotine 30 parts, water 1000 parts, and sodium carbonate 3 parts.

The details of the treatment are as follows. On the first day the anterior half of the body is dry-rubbed with a wisp of hay, followed by the application of the lotion over the same region. From 1 to 1½ litres of the lotion is sufficient. On the third day the same dry-rubbing and lotion are applied to the posterior half of the body. The treatment is then re-applied on the anterior half of the body on the fifth day, on the posterior half on the seventh day, and so on until the cure is complete. The application of lotion on any one day should never extend to more than one-half of the body.

In cases of generalised mange a definite recovery does not result until after ten applications of the lotion. In slight or early cases four or five applications suffice.

In cold weather the horses should be walked immediately after the lotion is applied, or, if that is not possible, should be rugged or sheltered. During the whole treatment the animals may be worked; and, if the feeding is good, neither the treatment nor the mange causes debility.

The author's clinical observations show that after two or three applications of the lotion the pruritis disappears and the case seems cured; but this recovery is only apparent. It requires ten applications to completely free the horse from acari.

In regions where the skin is crusted and depilated, the dry-rubbing is omitted lest it should cause erosion, and the lotion is applied as before stated. It is the lotion that cures, not the dry-rubbing.

In crusted regions, the crusts separate spontaneously at the end of ten to fifteen days. The skin recovers its flexibility; and this spontaneous desquamation is one of the signs that recovery is near. The application of lotion causes neither crusts nor dermatitis.

Lotions of nicotine are very injurious to acari, lice, etc., and disorganise sarcoptic colonies for a long time. Three applications of lotion are suffi-

cient to hinder all attempts at colonisation for a month. The author has observed that horses treated three times with nicotine lotions remained more than a month without showing any recrudescence of the disease. This prolonged injurious effect of nicotine upon colonies of acari renders treatment by tobacco juice very adaptable to all the conditions of campaigning life.

It may be objected that nicotine lotions have been known to cause intoxication; but the author says that in thousands of horses, he has not had one case of poisoning.

Treatment with nicotine is also to be recommended for psoroptic mange of the horse.—(*Revista de Veterinaria de Espana*).

#### IS CONCEPTIONAL RABIES POSSIBLE?

P. Remlinger, in April last, reported the results of his experiments upon this question to the *Société Biologie*. The possibility of conceptional rabies supposes the presence of the rabies virus in the sperm or the ovule. Various authors have already reported negative results of examinations of the semen for rabies virus; Blasi and Travallo alone obtained positive results. Remlinger is not aware of any investigations upon the presence of the virus in the ovary.

Remlinger carried out four series of experiments upon 33 rabbits and 51 guinea pigs. Into these animals he injected emulsions of the contents of the seminal vesicles, testes, and ovaries of guinea pigs which had died of rabies. In the first three series the injections were made simultaneously under the dura mater and into the muscles of the neck, and in the last series by the latter method alone. In the first series the emulsion was of the contents of the seminal vesicles, in the second of testes, in the third of ovaries, and in the fourth of a mixture of the contents of seminal vesicles and testes or ovaries.

None of the 84 experimental animals contracted rabies; and all were under observation for sixteen months after the experiments, a period more than sufficient for the development of the disease. Remlinger therefore concludes that conceptional rabies does not exist, and that all the cases of "hereditary rabies" proceed from a placental contamination.—(*Revista de Higiene y Sanidad Pecuarias*).

#### THE PASSAGE OF THE RABIES VIRUS FROM THE MOTHER TO THE FŒTUS.

The importance of this question, and the rarity of published cases, have led A. Lanfranchi and F. Lenzi to report the following new case.

The subject was a young bitch, which was brought to the authors suffering from dumb rabies, and died a day or two later. A post-mortem examination was made immediately after death, and revealed the presence of seven fœtuses at term. Negri's bodies were sought for in scrapings and in fixed and stained sections from the region of Ammon's horn in both mother and embryos. The result was positive for the mother, but negative for the embryos.

Biological tests were then adopted. Medullary extracts from the mother and all the fœtuses were injected into rabbits, with every precaution to guard against error. Some rabbits were injected subdurally, others into the anterior chamber of the eye, and others intramuscularly. All the rabbits injected died of rabies.

Contrary to the views of Loir and of Conradi, the authors saw no evidence that the virus had become attenuated in its passage from the mother to the offspring.

Their observations, therefore, lead them to the conclusions that (1) the rabies virus, in the infected bitch, may cross the placental filter to infect the fœtus, and that (2) filtration across the placenta, in dogs at least, does not produce an attenuation of the virulence.—(*Revista de Higiene y Sanidad Pecuarias*).

#### Prosecution by R.C.V.S.

At the Dorking Petty Sessions on Wednesday, Nov. 20, John Akehurst, of Capel, was summoned on two informations with having unlawfully acted and described himself as a veterinary surgeon, contrary to Section 17 of the Veterinary Surgeons Act, 1881. There was no appearance for the defence.

Mr. M. H. Haygarth, of Horsham, prosecuted, and said the proceedings were instituted by the Royal College of Veterinary Surgeons under Section 17 of the Veterinary Surgeons Act of 1881, which provides that, "if after the 31st day of December, 1883, any person other than a person who for the time being is on the Register of Veterinary Surgeons, or who at the time of the passing of the Act holds the veterinary certificate of the Highland and Agricultural Society of Scotland, takes or uses the title of veterinary surgeon, or veterinary practitioner, or any name, title, condition, or description, stating that he is a veterinary surgeon or a practitioner of veterinary surgery, or of any branch thereof, or is specially qualified to practise the same, he shall be liable to a fine not exceeding £20." Explaining the facts, Mr. Haygarth said that in April last a Mr. Swire, of Warnham, bought a pony at Messrs. Crow's Auction Market under a warranty, and had her examined by Mr. Akehurst, who gave the following certificate: "April 29th, 1918. I have this day examined a bay pony for Mr. Swire, and find her very lame on her off hind leg. J. Akehurst, Vet. Surgeon, Capel." The pony was returned to Messrs. Crow. Mr. Swire was informed that the certificate was not in order inasmuch as Mr. Akehurst was not a veterinary surgeon. Mr. Swire thereupon saw Mr. Akehurst, who said he was a registered man, which, in fact, was not the case. If the Magistrates were satisfied that defendant had contravened the Section he would ask them to inflict such a penalty as would be a deterrent in the future, not only to defendant but to others. It was not right to gentlemen who held the degree of M.R.C.V.S. that unauthorised persons should act in this way, nor was it fair to animals that they should be left to the tender mercies of unqualified and unskilled persons.

Mr. Swire, of Blackboro, Ditchling, and late of Hingfold Farm, Warnham, said that when he took defendant's certificate to the auctioneers it was disputed on the ground that it was given by an unqualified man. He then saw the defendant, to whom he said, "You are supposed to be an unqualified man, and I am afraid there will be some litigation in the matter."

Defendant replied: "I'm not afraid of that. I'm a registered man." Witness said, "I suppose you are referring to 1881?" and defendant said, "Yes, I am."

Mr. Haygarth, having given formal proof that defendant was not a registered veterinary surgeon, the Magistrates convicted, and imposed a fine of £5 including costs.

[Both Solicitor and Magistrates—the one in his statement, and the others by the light fine—appear to have overlooked the preamble of the Act, which describes it as "provision . . . to enable persons requiring the aid of a veterinary surgeon for the cure," etc.]

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

John Allan, Castle Douglas,			
Kirkcudbright	£1	1	0
T. G. Browne, Prof., R.V.C., Ireland	1	1	0
J. A. Griffiths, New Langenburg, E. Afr.	1	1	0
J. Hughes, Welshpool	1	1	0
S. T. Jackson, Capt. A.V.C.	1	1	0
J. H. Ripley, Hurst Green, Sussex	1	1	0
Previously acknowledged	1088	13	11
	£1094	19	11

#### CATTLE INSPECTION— COMPULSORY v. PERMISSIVE.

Sir—May I express the earnest hope that with the advent of the "Ministry of Health Bill" our Council will take strong steps to see that the Profession is entrusted with its proper work with regard to tuberculosis. When one realises that 75 per cent. of cases of cervical tuberculosis in children are of bovine origin it is obvious how essential the work of the veterinarian is in the proper and regular inspection of milking cows—the application of the tuberculin test, and the bacteriological examination of milk, etc.

The time is now opportune for the Representatives of the Profession to take a strong hand, and it is to be hoped that this will be done, not only for the sake of ourselves, but what is more important, for the State in general, both for the present and future generations.

I would suggest that our Council approach the Local Government Board to take action to ensure that the various local authorities should act in a more uniform manner. It is the rule in some counties to have the markets inspected by their veterinary inspectors, but in others this is not the case—the result is obvious—sheep-scab and other diseases are spread from the county in which inspection is not carried out to neighbouring counties. In Staffordshire, for instance, no inspection is carried out, yet in Warwickshire, which it adjoins, the markets are inspected—the distance between markets being quite small.

If the inspection is necessary in one county why not in another? The police of one county where inspection is performed are left wondering as to why a market one mile away but in another county is not so inspected, and this wonderment is aggravated when an outbreak occurs which is traceable to diseased animals being exposed in the markets of the adjoining county! Surely something should be done to ensure uniformity of action in the carrying out of preventive measures against contagious diseases.—Yours etc.,

M.R.C.V.S.

November 1918.

#### A CURIOUS DOCUMENT.

Recently there came before the writer's notice a document emanating from a M.R.C.V.S., and Local Veterinary Inspector of the Board of Agriculture, pertaining to the examination of a filly. The document states "At the request of — I have this day examined a brown Clydesdale filly, two years off, and number — in the sale catalogue. In my opinion the inside of the near fore coronet is slightly enlarged and is stronger than the inside of the off coronet." Then follows signature with the letters Sg. in front thereof.

Apparently it would be a misnomer to call the above a certificate. It is not a letter, and it is really very difficult to state exactly what it is. But one thing is certain—it is a worthless document to give to a client, and if it were given with the object of helping a client to get something knocked off the price of the abnormal animal, it will not fulfil its object.

The granting of such documents by qualified men shows that there is much room for progress in the profession. What can auctioneers and lawyers think of us when they peruse such emanations? It is to be noted that (1) the description of the animal is not fully given, (2) neither is the date or place of sale, and (3) no opinion is given as to the unsoundness or soundness of the animal.

F.R.C.V.S.

#### "'FLU' CAUSED BY BAD BACON."

Dear Sir,—I have noticed that in several papers complaint was made at a meeting of the Newcastle Food Vigilance Committee that the influenza epidemic was caused by bad bacon; and it was said that a local doctor had treated 400 patients for swine fever instead of influenza, and found the treatment efficacious.

I was visiting a medical friend the other day, and he was quite of the opinion there was something in it. It would be interesting to know what line of treatment this Newcastle medico took. The Board of Agriculture and Fisheries, and the veterinary profession in general will feel indebted to this man if he has at last got on the right track in the treatment of swine fever. No doubt he is more advanced in the pathology of swine fever than we are.

Possibly the S.F. serum treatment has been administered to all "in-contact animals"—himself included.

Yours faithfully,

T. F. HALL, M.R.C.V.S.

Saffron Walden.

#### NOTES ON BOOKS.

NOTES ON MEAT AND FOOD INSPECTION FOR SANITARY INSPECTORS. By JOHN T. COWDEROY, Chief Sanitary Inspector, Borough of Kidderminster. Second Edition. Pp. 78, exclusive of index. Price 2s. 6d. net. (The Sanitary Publishing Company Ltd., 8 Bream's Buildings, London, E.C. 4. 1918).

In his preface to this little "remembrancer," as the author calls it, he describes it as "an index to larger works" and "so arranged that the busy inspector may quickly arrive at any point."

This aptly summarises the book, which is intended for part-time food inspectors in the smaller towns rather than for whole-time men in the larger ones. Within these limitations, the volume is likely to do good. It contains a little over 70 pages of "notes," an index exceeding two pages, and one or two blank leaves for memoranda. The notes are very concise, and cover the principle diseased conditions met with in meat and food

inspection, various points to be noticed in examining carcasses and organs, the positions of the chief lymphatic glands, the most important legal clauses governing the duties and powers of food inspectors, and similar matters. The whole is necessarily very condensed and fragmentary; but still the author has compressed a good deal of information into a very small space. So far as it goes, the work is well done; and, though it is a long way from meeting the needs of veterinarians and whole-time food inspectors, there are others who will find it helpful. Veterinary surgeons concerned in meat inspection refer to very different books for guidance; but their work may bring them into touch with men to whom this little volume may usefully be recommended.

**VETERINARY HANDBOOK AND VISITING LIST.** By THOMAS B. ROGERS, D.V.S. Price 6s. net. (J. B. Lippincott Coy., Philadelphia and Henrietta St., London).

This little book belongs to a class well known to English practitioners. The first 119 pages contain a variety of information useful to veterinarians, chiefly arranged in tabular form. Among the most useful items are tables of posology, poisons and their antidotes, incubation periods of the commoner animal contagious diseases, durations of pregnancy in the various domesticated animals, the strength of the U.S.P. tinctures most used in veterinary work, and the relative value of metric and apothecaries weights and measures, with some account of prescription writing, and a few elementary hints on bacterial therapy. The posological table is good and full, and contains a useful feature in the form of blank columns for the clinician's addition to it; but the fact that it is based upon the U.S. Pharmacopœia is a distinct disadvantage to English practitioners. The only item which is really useless to English readers is a summary of a new United States Revenue law governing the sale and use of certain narcotics.

The visiting list is conveniently arranged, and contains room for a year's work at an average of 54 clients per month. This does not represent a large practice; but not every client need be inserted in such a list. Altogether the book will be useful to those who like such a collection of information arranged in a handy form; but its price certainly seems high, and its casting upon U.S.P. lines is an undeniable drawback here.

### ARMY VETERINARY SERVICE

War Office, Nov. 22.

The following are among the Decorations and medals awarded by the Allied Powers at various dates to the British Forces for distinguished services rendered during the course of the campaign (the King has given unrestricted permission in all cases to wear the Decorations and medals in question):—

*Conferred by the President of the French Republic.*

CROIX DE GUERRE.

\* \* \* \*

Capt. W. J. BAMBRIDGE, A.V.C., Spec. Res.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Nov. 22.

REGULAR FORCES. ARMY VETERINARY CORPS.

Temp. Maj. (actg. Lt.-Col.) R. J. Stordy, D.S.O., to be actg. Col. whilst holding the appt. of Dep. Dir. of Vety. Servs. (Oct. 14).

Capt. R. W. Mellard, D.S.O., relinquishes the actg. rank of Maj. on ceasing to hold the appt. of Dep. Asst. Dir. of Vety. Servs. (Oct. 1).

Cpts. to be actg. Majs. whilst Dep. Asst. Dirs. of Vety. Servs.:—H. G. Tabuteau-Herrick, M.C., Spec. Res.; F. Hopkin (T.F.) (Oct. 2).

Nov. 26.

Temp. Maj. T. C. Evans, M.C., Can. A.V.C., ceases to be secd. for duty with War Office (Oct. 10).

Nov. 27.

Capt. and Bt. Maj. (temp. Maj.) G. E. Tillyard to be actg. Lt.-Col. whilst holding the appt. of Asst. Dir. of Vety. Servs. (May 29).

Temp. Lts. to be temp. Cpts.:—W. S. Petrie, J. P. Rice (Nov. 12).

TERRITORIAL FORCE, ARMY VETERINARY CORPS.

Nov. 26.

Capt. W. K. Barron to be actg. Maj. whilst comdg. a Vety. Hospital (Nov. 13).

India Office, Nov. 26.

To be Lieut.:—K. Hewlett (April 1, 1917).

### R.A.V.C.

By Royal Warrants published in Army Orders on Wednesday, 27th inst., the Army Veterinary Corps (together with the A.S.C. and A.O.C.) are to have the distinction of "Royal," in recognition of "the splendid work" which they have performed during the war.

### OBITUARY.

M. ALLAN, M.R.C.V.S., "Birchmount," St. Leonards Rd., Windsor. Graduated, Lond: May, 1897.

Mr. Allan died 23rd November, aged 44 years.

CHARLES WM. GREGORY, M.R.C.V.S., Temple St., Bristol. Lond: May, 1861.

Death took place 17th November, at the age of 80.

ROBERT MCNAE, M.R.C.V.S., Maxwelltown, Dumfries. Lond: April, 1873.

Mr. McNae passed away 21st November, aged 71.

### Personal.

GIBBS.—On the 20th Nov., 1918, at the Château de Fossé, Le Fossé, Seine Inférieure, France, to Yvonne (née du Fossé du Bosmelet), wife of Lt.-Col. H. E. Gibbs, D.S.O., A.V.C.—a daughter (Viviane).

At a monthly meeting of the Council of the Pharmaceutical Society of Dublin, on Nov. 12, the Registrar read a letter of appreciation and thanks from Mr. John McBirney, M.R.C.V.S., M.P.S.I., on the completion of his term of office as Examiner in Chemistry.

### Charge of Cruelty at Reigate— mange and starvation.

At the Reigate Police Court, on Thursday, Nov. 7th, Jenny Ethel Elizabeth Hamilton, of the Cedars, South Park, was charged on remand with ill-treating ten dogs and four cats. The magistrates who tried the case were his Worship the Mayor (in the chair) and Mr. W. H. Bagaley.

Mr. Polhill, of the R.S.P.C.A., prosecuted, and Mr. Jenkins defended.

The evidence of P.S. Sturt, who visited the Cedars with P.S. Hood was read over. Cross-examined, witness said they found the four cats on the table, and they appeared to be in a starved condition. When the dogs

were fed at the police station they were very ravenous, and tried to force their way out of the boxes to get at the food. There were about 14 lb of dog biscuits found on the premises.

In reply to Mr. Jenkins: As far as I know I should say they were suffering from mange and had been neglected. They had not received proper treatment. So far as I could see no attempt had been made to relieve the suffering of the dogs.

In what way do you mean nothing had been done to relieve the sufferings?—By dressing and washing them. I suggest they had not received sufficient food.

Did you go over the house?—Yes.

And what food did you find?—About 14 lb of dog biscuits, some 20 to 30 lb of oatmeal, and 4 or 5 lb of rice.

P.S. Hood stated he spoke to defendant when P.S. Sturt and he visited the Cedars on the 30th ult. He told Miss Hamilton they were police officers and had been instructed by the Head Constable to call and see her dogs.

They saw a light Pomeranian, which was aged and very mangy. The right eye was missing, and the hollow was full of matter. The left eye was affected and almost blind. It was in a very neglected condition.

Defendant brought from the interior of the house a cross-bred Bedlington Irish terrier. There were humoury sores on the eyes, ears and body.

There was no complaint made with regard to the third and fourth dogs shown to them.

The fifth dog was in fair condition. It was aged, but was suffering from a skin disease.

A brown mongrel had skin disease on chest and legs, and was very weak in the hind quarters. It seemed to be crippled; otherwise it appeared to be in a fair condition.

A smooth-haired fox terrier had skin disease all over the body and head, and was in poor condition. An Irish terrier was in a very poor condition. It had skin disease all over the body and legs, scabs and sores on the haunches, probably due to scratching.

A white fox terrier bitch in poor condition, and covered with a skin disease.

A toy bull terrier in a very emaciated condition, covered from head to foot with a skin disease. The body was covered with sores, and it was very weak.

Miss Hamilton then said, "That's all the dogs I have. You have seen them all." He asked her if she had any cats, and she replied, "Yes; they are out." He insisted upon seeing the condition under which they were kept, and went into the house with P.S. Sturt. The house was almost devoid of furniture. There were a few packing boxes about the house, and a number of small boxes.

On going into the kitchen they saw four cats on the table in a crouching position. They were in a poor condition, and suffering from mange, and had no life at all in them.

He also saw in a box a cross-bred terrier bitch in a very emaciated condition. It was covered with skin disease from head to foot, and almost too weak to stand. He raised it on its feet, and it fell down again. It was really nothing but a bag of bones.

In the scullery they found a black mongrel bitch with scarcely any hair on the body. It was in a shocking emaciated condition, and the bones almost protruded through the skin. She was suffering from a skin disease.

He said to the defendant, "Why did you not produce these two dogs at the inspection?" She hesitated and seemed confused, and, said, "I had forgotten." They found a quantity of dog biscuits, oatmeal and rice in different parts of the house. There was no receptacle for either food or water for the dogs, and there were no signs of any food having been given to the dogs. The stench was so bad that they frequently had to leave the

house to get a breath of fresh air. The twelve dogs and four cats were taken to the police station, where they were fed, and they ate the food ravenously. Their thirst was almost unquenchable. They were fed three times that day, and were ravenous on each occasion. He had had the dogs and cats in his charge since then. With the assistance of several ladies they had been looked after, fed, watered and exercised. With the exception of the toy bull terrier they had greatly improved in bodily condition. The cats had also improved.

Inspector Discombe, R.S.P.C.A., spoke to being present when the dogs were examined by P.S. Hood and P.S. Sturt, and gave corroborative evidence as to the condition of the dogs. There was no evidence that the dogs had been dressed, and they had received no treatment at all. In his opinion the dogs and cats had suffered very much from not having received proper treatment. Since the dogs had been in charge of the police they had greatly improved, with one exception spoken to by the previous witness.

Mr. Jenkins: In what way do you say they have not received proper treatment?—They had not been dressed or washed or disinfected. They have been left there and nothing done for them.

How long do you suggest treatment had not been given to them?—For seven days at least.

Do you suggest the cats were suffering from mange?—Yes.

Mr. C. A. Squair, M.R.C.V.S., Veterinary Inspector to the Borough of Reigate, gave evidence as to the condition of the dogs and cats. The French poodle (described by Sergt. Hood as a black mongrel) was in a horrible condition. He had marked it down in his notes "diabolical." It was very emaciated, and the bones were almost protruding through the skin.

In reply to the Clerk, witness said all the dogs were more or less emaciated, and had apparently been neglected as regards food and treatment. When they were in the boxes at the police station they fought for their food.

Mr. Polhill: If these dogs had received proper care and treatment could they have got into the condition in which you found them?—Most certainly not.

What do you suggest should be done with the ten dogs?—I certainly should have them destroyed both from the fact they have skin disease, and from the national point of view, as the food question is a difficult one.

Can you say these dogs had any treatment or dressing for skin disease?—No; except one of them, which defendant brought to my surgery about two months ago.

You have heard oatmeal was found at the house. Would that be proper food to give to the dogs?—Not for dogs suffering from skin disease.

Do you say these dogs were suffering from pain as the result of their condition?—Yes. I think there is no question about it.

Mr. Jenkins: What sort of food do you suggest they should have had?—Plain dog biscuits.

So if they had dog biscuits they would have been properly fed?—They ought to have been in a better condition. When suffering from mange they require more food.

Witness was questioned as to defendant seeing him in respect to one of her dogs, and he said he suggested it should be destroyed. He asked defendant at the time if she had any other dogs, and she said, "Yes, five or six others," and that they associated with each other. Defendant also told witness the other dogs were free from disease, and he then gave her medicine for chronic eczema.

Mr. Polhill: When did you see the dog again?—About three weeks ago.

What was its condition?—It was slightly improved.

Did this lady at any time ask you to go and see the other dogs?—No.

The Clerk: Do you consider it would be cruel to keep these dogs alive?—No, not the whole ten. It would be very cruel to keep some of them alive.

Mr. Charles Malvisi, M.R.C.V.S., York Road, King's Cross, gave corroborative evidence, adding that it was his opinion that all the dogs had been cruelly treated, and had no medical treatment of any kind. The whole of the ten dogs ought to be destroyed for the sake of the dogs and for the sake of others.

Mr. Polhill: If these dogs had received reasonable care and treatment could they have got into the condition you found them?—No. Had they been treated in the first place for the disease they would have got over it.

What do you say about the cats?—They have got the mange in a mild form. Their bodily condition is fair, but for the sake of other cats I should destroy them.

Mr. Jenkins: Do you suggest all animals suffering from mange should be killed?—Yes; suffering as these are.

#### THE DEFENCE.

Defendant said she had been a member of the R.S.P.C.A. since she was a child. Her friends assisted in the foundation of the Society. "I gave a subscription yearly and won every case I took to them. I continued to subscribe until they had vivisectionists on the Council. Since then I have not given a farthing.

After you ceased to be a member is it a fact that the Society has persecuted you ever since?—Yes.

Mr. Polhill: I must protest against these statements.

They had a case against me a short time ago. I was prosecuted for some of the dogs that are mentioned in this case. The Bench dismissed the case.

Continuing, witness said since 1908 she had taken an interest in stray dogs, and had cared for them. She had had through her hands hundreds of them, and they had improved under her care. She had had them when in a bad condition, and had got them round, finding them good homes.

Mr. Jenkins: Is it a fact that you have devoted your life to try and improve the condition of these dogs?—Yes, since 1908, and have devoted every farthing I had to stray dogs and cats.

Have you done all in your power to support the dogs, and have the dogs been properly taken care of?—Day and night I have thought of nothing else.

Witness also told the Court she had consulted the College of Veterinary Surgeons and several veterinary surgeons in London about the condition of the dogs, and was doing all she could for them.

Mr. Polhill: Have you any objection to them being destroyed?—Yes, I have.

Do you object to the taking of life?—Yes, without a very good reason.

Witness, further questioned, said it did not occur to her the dogs were suffering from mange. She thought the dogs had tape worms, which often brought about an eruption of the skin.

John Jupp, a jobbing gardener, of South Park, stated he had purchased by orders of defendant, paunches for the dogs and fish for the cats.

Hilda Hood, of South Park, spoke to visiting Miss Hamilton on many occasions. She had been in the house almost every day, and had seen the food being prepared for the dogs. Dog biscuits, oatmeal and rice was prepared for the dogs, and fish was cooked for the cats. She had purchased by order of the defendant Boviline for the cats.

Mr. Polhill: What did you go to the house for?—To see the animals.

Do you know anything about dogs or their treat-

ment?—I am very fond of dogs, and know that they should have plenty to eat, and exercise.

Witness had several conversations with Miss Hamilton about the condition of the dogs, and she said it arose from different causes. She noticed the dogs were very thin, and suggested that two of them should be destroyed. Miss Hamilton told her she thought she could cure the dogs.

Mrs. Davis, of South Park, said she had been at defendant's house once.

Mr. Polhill: What reason had you for going to see the dogs?—Because I heard they were neglected.

When was that?—About five weeks ago.

What did you say to Miss Hamilton when you got there?—I asked her if I could see the dogs. She only showed me three. I asked to see the others. She said they were all in bed and tied up in other rooms, and might bite me.

What was the condition of the dogs you saw?—One seemed to have something wrong with his legs, and the eyes were rather bad. She asked me if I could tell what was the matter with the dogs. I told her I could not, except that one looked as if it had rheumatism or rickets.

Mr. Frederick Cousens, M.R.C.V.S., Surgeon to the Zoology Society, the Canine Society, and His Majesty the King, said he had known the defendant for a number of years, and that she had been in the habit of looking after stray dogs and cats from a philanthropic point of view.

Mr. Jenkins: She had been devoted to dogs?—Yes, it seems to me that it has been the one aim of her life to look after stray dogs, and she would be the last person to cause them any suffering.

Has she from time to time consulted you as to the treatment of the animals?—Yes; sometime personally, and sometimes over the telephone.

And you have prescribed, and have learnt subsequently that the animals have improved?—Yes.

Have you seen these animals?—Yes, to-day.

What is your opinion now that you have seen the dogs. Do you suggest they have been neglected in the way suggested?—May I put it like this? So far as the description of the dogs is concerned, that one given by first witness is accurate.

The Mayor: Did you see the dogs a week ago?—No.

Continuing, witness said the evidence of the second witness (Sergt. Hood) was exaggerated. Of course, no one could blame him for trying to get a conviction.

Mr. Polhill: I object to these remarks.

Mr. Jenkins: What is your opinion in regard to these dogs so far as Miss Hamilton is concerned. Do you think she has done what any reasonable person would do, having seen the dogs?—I can't answer what Miss Hamilton has been doing. I do think if a dog has skin trouble which causes irritation or internal parasitism, that dog would become thin even if eating good food.

Witness expressed the opinion that all the dogs could be treated satisfactorily and get well, notwithstanding some of them were aged. Certainly aged dogs did not respond to treatment the same as young dogs. As to the cats, they were in a much better condition than the dogs.

Mr. Jenkins: It is suggested that three dogs must be destroyed. What is your opinion?—If you listen to the witnesses in the box, yes; but it is my business to try and cure, and not kill.

Supposing you took these particular animals in hand, I suppose you are certain you could bring them round?—I should expect to bring them round.

Mr. Polhill: Do you agree that a number of these dogs have got skin disease in an advanced stage?—Yes; it is more or less chronic.

Don't you think it is desirable when dogs get to that

stage they should be destroyed?—I would say I would properly care for them.

Do you consider it cruel to keep these dogs alive?—Every dog has a right to live.

Would you take these dogs to your kennels?—Yes.

What would you do with these dogs if your advice were asked?—I would put them in hospital to be treated.

Mr. F. Wooff, M.R.C.V.S., Croydon, gave corroborative evidence.

The Bench retired, and returning to the Court, the Mayor said defendant would be fined £15, and ordered to pay £5 costs. The bench also ordered the dogs to be placed in the care of Mr. Cousens.—*Surrey Mirror*.

[The foregoing is somewhat abridged. It is stated that this case occupied the Court for more than four hours.]

#### Contamination of Milk.

The results of some experiments conducted in America show that it is the utensils rather than the barn that are largely responsible for the excessive bacterial contamination of milk. In one experiment: when all the utensils commonly used for handling the milk at the barn and in the dairy were thoroughly steamed, the milk had uniformly only about 5,000 bacteria per cubic centimetre, but if the steaming was omitted the bottled milk frequently contained several hundred thousand bacteria per cubic centimetre. The cans used for carrying milk are found to be a particularly prolific source of bacteria when they are washed at the dairy and returned to the farm without being thoroughly steamed and dried. The number of bacteria usually added to the milk by such cans was many times larger than the number that ordinarily get into the milk at the barn; the addition of a million bacteria per cubic centimetre of milk by such cans was not uncommon. It seemed to the experimenters that in an attempt to produce milk with low germ content, too much stress had been laid on practices of minor importance, and the influence of utensils badly steamed and not dried had been commonly neglected.

It was determined by a series of bacterial counts to what extent the condition of the milk was influenced by (1) the use of sterilised utensils, (2) the precaution of washing the udder and teats before milking, and (3) the reception of the milk in a small-top pail, which is described as being of the ordinary type, but with a fixed top having a small semicircular opening near the edge.

The results indicated that, with sterilised utensils, the bacterial numbers were 6306 per cubic centimetre, against 73,308 when they were not sterilised.

With udder and teats washed, the average was 2154; unwashed, the average was 4524.

By the use of a small-top pail the numbers of bacteria

were 750,000 per cubic centimetre, whereas with an ordinary pail the numbers were 1,200,000.

These workers conclude the above three factors, together with keeping the milk at a low temperature, to be the most important points in the production of fresh milk with a low bacterial content.

#### Goat-breeding in Ireland.

At a meeting of the Irish Goat Society, held at 9 Ely Place, Dublin, the Secretary, Miss K. S. Saunders, said they had made considerable progress within the last few years. Since the Committee meeting held in April, two promising branches had been started at Coleraine and Cookstown, and thirteen new members had joined, making a total of over 90 members in all. Owing to the acute shortage of milk the demand for goats had increased enormously since 1914.

The Society, had consequently resolved to establish a small goat farm at Trillick, Co. Tyrone. The Department of Agriculture gave the Society a small grant in 1916 towards the general expenses of running the farm. The number of goats and kids distributed throughout Ireland from the farm and district of Trillick in 1916 was over 50, but such was the ever-increasing demand that the Society in 1917 applied for a further grant from the Department, which was generously accorded. During the financial year 1917-1918 over 104 goats and kids were sent out from the farm at Trillick, and within the last six months over 64 goats and kids have been sold from the farm. Besides these sales, the Secretary arranged several purchases for different members of the Society, as well as many exchanges of stud goats.

A great deal has been done to ensure a high, all-round standard of milk production by means of careful selection of sires, and by steady breeding from the best stock. Over 40 male goats were distributed through the country last year. The Society also arranges an exchange of these goats among the different members, so that unrelated sires may be introduced into each district at suitable intervals.

In other countries, notably in Switzerland, the standard of milk production has been greatly raised by constant care in selection and breeding. By this means the time of lactation has been lengthened, and it has been found possible to produce an animal that will kid out of the usual season, and so ensure a supply of milk during the months when our native goats are dry. The manager of the goat farm mentioned that out of a herd of 15 milch goats, five were due to kid during November and January, thus plainly demonstrating that winter kidding is no longer a problem.

Miss Saunders, Trillick, Co. Tyrone, will be pleased to answer any questions with regard to goats and goat keeping.—*The Farmers' Gazette*.

## Feeding Cake from Rubber Seed.

Feeding trials have been made with rubber seed cake at the South Eastern Agricultural College, Wye, Kent. A feeding trial with cake made experimentally from kernels imported from Ceylon was carried out at the College during the latter part of 1912 and the beginning of 1913. A sample from this consignment examined at the Imperial Institute was found to be strikingly similar to linseed cake in composition. The chief difference is in the quantity of "fibre," which is only 5.01 per cent. in the case of Para rubber seed cake, against 9.10 per cent. in linseed cake. Like linseed cake, Para rubber seed cake may yield small amounts of prussic acid, and the amount furnished by this sample is rather high, but it produced no ill effects on the animals fed with the cake.

All attempts at feeding sheep with this sample of rubber seed cake failed. But the results with cattle-feeding were altogether favourable. The cake was fed to a pair of two-year-old fattening heifers, which readily ate the food. The quantity of cake was increased gradually to eight pounds per head per day, but this caused pronounced scouring, and even five pounds of Para rubber seed cake eaten daily with 56 lb of mangolds produced a slight laxative effect on these immature animals.

Further experiments with [another batch of two-year-old beasts confirmed this conclusion. Two of the beasts were killed at the conclusion of the experiments; the butcher reported the carcasses to be of first-class quality, and the beef of excellent flavour. One of these heifers had received six pounds of cake per day for ten weeks.

Six barren cows with an average milk yield of 1½ galls. per day, were fed with increasing amounts of the cake

until, at the end of a week, each animal was receiving 14 lb of cake per day. The cake was the only concentrated food supplied to the animals, and the ration was continued for six days without any marked change in the animals' excreta. The ration being richer than that previously allowed, the yield of milk rose, but the percentage of fat in the milk was practically unchanged. Butter was made from the milk produced during the first three days, and again from that of the second three, and in each case the texture, smell and flavour of the butter was considered to be unaffected by the change of concentrated food.

These cows were fattened while still in milk, the daily quantity of rubber seed cake being reduced from 14 lb to 8 lb., and 4 lb of other cake added. The cows remained in a very healthy condition, and maintained a high milk yield until they were intentionally dried off about a month before sale to the butcher. The increase in live weight over an average fattening period of nine weeks was 1.7 lb per cow per day, and the milk yield was 0.85 gallon per cow per day, the cows being in milk an average of six only of the nine weeks.

The value of Para rubber seed cake as a food for cattle has been clearly established by these experiments. It now remains to secure the co-operation of the rubber planting companies to place the production of rubber seed oil and rubber seed cake on a commercial basis, and so set up a new industry within the Empire. The mother country would gain a valuable addition to its cattle feeding stuffs, while the rubber producing Colonies would profit by the utilisation of what has hitherto been a waste product. Vast quantities are at present allowed to go to waste on the rubber plantations in the Malay Peninsula, Ceylon, Java, and other parts.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1587.

DECEMBER 7, 1918.

VOL. XXXI.

## PUBLIC HEALTH REGULATIONS.

A correspondent, in a letter printed last week, calls attention to the question of "Compulsory v. permissive Cattle inspection," and some other subjects suggested by the advent of the Ministry of Health Bill. All this is part, and a very important part, of the "re-construction" which we are promised. Next year we may have to consider a multitude of very wide and complex subjects, many of them probably overlapping. Public health is one of the most intricate of these. A great deal of it does not directly concern our profession; that portion which does is a larger subject than at first sight appears.

At present all our veterinary public health administration, except control of the few scheduled diseases, is inco-ordinate and inadequate. Local regulations show a grievous lack of uniformity, are often insufficient to meet individual requirements, and are lamentably so in the gross when we consider national requirements. Even a casual examination of our methods will reveal many points requiring alteration; but both study and consideration will be needed to devise a system which shall satisfactorily replace them.

Our correspondent of last week urges uniformity in the veterinary inspection of markets and fairs, and instances counties in which such inspection is performed and others in which it is not. We may all well agree with him so far; but the mere enforcement of uniform "veterinary inspection" upon local authorities is not sufficient. It is necessary also to ensure as far as possible that the inspection shall be efficient—as, for instance, to provide that the inspectors shall have time to do their work properly. It is common knowledge that disease has been spread from markets which were not inspected. It has also certainly been spread from markets which were said to be "inspected," but at which the veterinarians were too over-worked to accomplish an inspection worthy of the name. This fairly illustrates the whole subject—our present system is so unsatisfactory, both in construction and working, that the indication of one weak point generally suggests other related ones in equal need of amendment.

The subject is well worth consideration by professional societies; and the discussion and publication of specific instances of differences or defects in local regulations might be especially valuable just now, but it would be well to recognise that an attempt to approach a Government department, made by an isolated Society with no title to represent the profession, would be more likely to do harm than good.

## THE COWSHED INFECTIONS OF NEWLY-BORN CALVES, AND SERO-PROPHYLAXIS.

Prof. Pietro Stazzi, of Milan, has written a report of his work in this direction. In his experience, the infections in question have almost always been due to the *bacillus coli*, and great success has been obtained from the use of polyvalent sera prepared by means of different strains of this microbe. Stazzi's conclusions may be summarised as follows:—

1. Several thousand tests have proved that bovine anticolibacillary serum is an excellent means of prophylaxis and treatment in cow-shed infections of newly-born calves. More than 95% of these infections, at least in Lombardy, whatever clinical forms (dysentery, polyarthritis, bronchopneumonia) they may assume are colibacilloses.

2. In the more common cases of *extra-uterine* infection (which occurs either by the digestive tube or by the umbilical cord) one or two injections of 20 c.c. of serum suffice to protect the newly-born calf against the contagion. The injections may be subcutaneous, intramuscular, or, better, intraperitoneal.

3. In rare cases of enzootics with *endo-uterine* infection, to arrest the mortality, it is necessary to inoculate the cows some days before parurition with the same serum, in doses of from 40 c.c. to 80 c.c., and afterwards to perform the usual inoculations (preferably into the peritoneum) upon the newly-born calves.

4. In cases of enzootic, in which calves which are protected by the serum from the septicæmic form of the disease afterwards show colibacillary complications of pneumonia, arthritis, etc., it is well to follow the injection of serum, after two or three days, with the injection of an autogenous vaccine.

5. The serum gives the maximum results (protecting 100% of newly-born calves) when it is prepared from the same microbial strain that has caused the enzootic. Hence a special serum should be prepared for every enzootic. When this cannot be done, the best possible results are obtained by preparing a polyvalent serum from given groups of enzootics which have developed in a territory. Several such polyvalent sera are now prepared in Italy for use in different parts of the country. Cases may occur in which, though the serum producing animals are in a state of advanced hyper-immunisation, and their serum is active against the bacterial strains which have been used to produce it, it has little or no effect against an enzootic caused by different strains. In such the serum may, in a few days, be rendered active against the new strains also by the intravenous inoculation of some loops of culture.

Numerous tests prove that if the greatest possible number of strains are used in the preparation of serum, and these can be subdivided among a good number of serum-producing animals, it is possible to obtain polyvalent sera of high efficacy against almost all enzootics.

Along with the use of the sera, Stazzi, of course, advises disinfection of cow-sheds, and all possible hygienic care of the animals, both before and after parturition. Among other measures he recommends allowing the calf to suck the first milk from the cow, in order to favour the elimination of the meconium.—(*La Clinica Veterinaria*)

#### THE PREVALENCE OF BOVINE TUBERCULOSIS IN THE PUNJAB.

G. Taylor contributed an important note upon this subject to the *Indian Journal of Medical Research* of January last. Hitherto tuberculosis in cattle has not attracted much attention in India, the general idea is that the native cattle are comparatively free from the disease. This idea appears to be erroneous, according to the data furnished by Taylor in this paper, which is based upon observations recorded subsequent to the institution of a proper system of meat inspection at Ferozepore Cantonment slaughter-house, Southern Punjab.

The inquiry was carried out from August, 1915, to March, 1916, during which period 3276 animals were admitted for slaughter. These animals had almost all arrived from the Central and South-eastern districts of the Punjab, and were all of the indigenous breed. The method of meat inspection entailed the examination of all animals while still alive, and thus 575 of the above animals, or 17·8% were rejected as not likely to be fit for human consumption on account of innutrition, disease, or old age. It is probable that a good many of these cast animals were suffering from chronic tuberculosis. Of the remaining selected animals 95, or 3·5 per cent., presented after slaughter what appeared to be macroscopic tuberculous lesions. In 60 of these cases tubercle bacilli were demonstrable in the lesions on microscopic examination. The distribution of the lesions in each of the affected animals is depicted in tabular form. The animals found to be tuberculous were all females; this would be due to the fact that cows and heifers form by far the largest source of meat supply. The lesions in the selected cattle were nearly all of a localised nature.

In all but two cases the disease was confined to the thoracic cavity. The bronchial and mediastinal glands were most commonly affected, either alone or associated with invasion of the lungs. In many cases the lesions were so limited in extent that they were only discovered after very careful search. In the two cases noted there were lesions in the mesenteric glands in addition to those in the thoracic cavity. In only one case was anything like a generalised condition of the disease found—in a cow about nine years of age. This was the only case in which the udder was affected.

During the year 1916-17 (1st April to 31st March), 4610 animals were brought for slaughter. Of these 821, or 17·8 per cent., were rejected as unfit for

slaughter. Of the remaining animals, which were slaughtered, 125, or 3·3 per cent., were found infected.

The above figures appear to indicate that tuberculosis is by no means uncommon in the Punjab. It is a striking fact that hitherto practically all the cases recorded have been confined to Northern India, the Southern Provinces apparently being free. Further investigation on this subject is required.—*Trop. Vet. Bulletin*.

CASE RECORDS. Ambulatory Clinic, N. Y. State Veterinary College. Prepared by D. H. UDALL, and F. F. KOENIG.

#### GASTRIC ULCER.

An eight-months-old Guernsey heifer in good condition was found at pasture in the morning lying down and reluctant to rise; all usual food was refused. The nights were cool and the grass had been frozen.

*Symptoms.* The animal was found down, weak and depressed. On rising the back was arched, the hair rough and dry, eyes sunken, conjunctival mucous membrane pale and icteric. Pulse 80, Resp. 12, Temp. 99. Extremities cold. Digestive system: Complete anorexia, m.m. of mouth cool, moist and sticky, slight rumination, abdomen usual size, very active peristalsis, evacuations frequent and watery.

*Clinical diagnosis.* Acute gastro-intestinal catarrh predisposed by cold nights and induced by eating frozen grass.

*Treatment.* Placed heifer in a box stall and covered with a blanket. Administered 20 c.c. of camphor liniment (1:4) per subcutis. Bismuth subnitrate 3 ss. R̄ Fluid Extract zingiberis 3 ss., Fl. Ext. nucis vomicae m.xx. M. Given in water as a drench. Prescribed 30 grains of sodium sulphocarbonate three times daily. R̄ Fl. ext. nucis vomicae 3 ii, Fl. ext. zingiberis 3 iiss, alcohol 3 iiss. Give in four doses during the next 24 hours. Feed two quarts of warm milk three times daily.

The second day the heifer was much brighter, eyes were less sunken, and there was more colour in the m.m. The milk had been taken as directed. Pulse 120, temp. 99·4. Peristalsis still very active, evacuations watery. Administered bismuth subnitrate 3 ss. Digitalen 1 c.c. per subcutis. Prescribed R̄ Fl. ext. zingiberis 3 iv, Spiritus ammoniac aromatis 3 iv, Fl. ext. nucis vomicae 3 ii. M. Sig. Give an ounce dose at two-hour intervals from 12 m. to 10 p.m. Give 120 grains of sodium sulphocarbonate three times daily.

On the third morning the animal was much better. A tonic was left and directions to call at once if improvement was not maintained.

On the seventh day the condition was reported as very much worse. Patient was found down and unable to rise without help, the left eye was swollen shut and discharging pus. Pulse 72, temp. 98·8. Extremities cool. The usual amount of milk was taken. Mouth dry and cool, peristalsis very active, evacuations watery and foetid. Administered oil of camphor and bismuth as on previous days, and

prescribed stimulants of aromatic spirits of ammonia with nux combined with large doses of sulpho-carbolates.

Eighth day no improvement. Temp. 98.4. Death occurred in the afternoon.

*Autopsy.* Marked cedematous thickening of the mucosa of the abomasum. The mucous membrane was elevated in folds of one to two inches high, arranged so closely that they could be turned like leaves. On the folds were numerous ulcers varying in size and depth, and a few necrotic spots. The surface was thickly covered with a dirty greyish mass of meal-like consistency. The liver was very yellow and friable, the kidneys hæmorrhagic and friable. The intestinal mucosa presented a slight catarrh.

The symptoms of gastric ulcer in bovines are quite variable, and do not often indicate clearly the real lesion. Salvisberg has recently described four cases in which the symptoms were divergent. *Case I* died suddenly without showing any previous symptoms. Blackleg was suspected, but the autopsy showed three perforations of the abomasum that had resulted in exudative peritonitis. The mucosa was cedematous and covered with numerous ulcers. The perforations were small, resembling holes made with a leather punch. *Case II*—a three-year-old cow that had shown diarrhoea for several days. Appetite and rumination completely lost. Pulse 86, resp. 20, temp. 104. Eyes sunken, profuse diarrhoea. Diagnosis of enteritis or gastric ulcer. He mentions the use of hydrochloric acid in making a diagnosis in this case, and infers that it aggravates the symptoms. Autopsy showed an cedematous mucosa, and numerous ulcers. *Case III* he regards as the most typical of this disease. The victim was a cow at pasture suspected of having gastric strongylosis. Chronic diarrhoea with watery, gaseous foetid evacuations, marked emaciation, and failure to give milk led to a diagnosis of chronic specific enteritis (Johne's Disease). On autopsy the intestinal mucosa was normal. Abomasum found cedematous, spiral folds thickened and ulcerative. *Case IV* was similar to *II*. All four cases were seen in August to November.

#### ACUTE GASTRO-INTESTINAL CATARRH.

A two-week-old Guernsey heifer had been dull and eaten poorly for four or five days, the faeces had been very firm and slightly streaked with blood.

*Symptoms.* Depression. Condition poor. Temp. 103.2. Appetite poor. Faeces almost white, very firm, and slightly streaked with blood.

*Treatment.* Administered 10 c.c. oil camphor (1:4) per subcutis, ol. ricini  $\frac{3}{4}$  iii, followed by enemas and the removal of a small quantity of firm faeces. Prescribed R. Fl. ext. zingiberis  $\frac{3}{4}$  i, Fl. ext. nucis vomicae  $\frac{3}{4}$  iv, alcohol q.s.  $\frac{3}{4}$  ii. M. One tablespoonful three times daily in milk.

Fifth day, calf was brought to the clinic. On this morning about one quart of milk was taken, but the general history was that of anorexia, depression, weakness, and constipation. Up to this time the calf had received 10  $\frac{3}{4}$  of castor oil.

*Symptoms.* Too weak to rise, skin dry and tense, expression dull, eyes slightly sunken. Pulse 110, resp. 48, temp. 102.2, nose dry and cold, extremities cold. Digestive system: Oral m.m. highly congested. Tympany on percussion over fourth stomach, abdomen reduced in size. Faeces yellow, pasty, foetid, and contained small, coagulated clumps. The skin around the anus was macerated with accumulations of faeces. Administered ol. camphorae 35 c.c. per subcutis during the day and evening in four doses. Enemas of normal salt solution were given at two-hour intervals, and each time a variable amount of pasty faeces was removed. A considerable amount of the salt solution was retained. 100 c.c. of normal salt solution was given in the jugular vein, and  $\frac{3}{4}$  i of bismuth subnitrate was given in milk. The feed consisted of about 250 c.c. of equal parts of milk and lime water containing 8 c.c. aromatic spt. ammonia three times daily. Also administered gr. 1/15 strychnine sulphate per os.

Sixth day, less depression than yesterday, found standing in the morning, less congestion of the oral m.m., peristalsis active, evacuation slight and pasty. Pulse 75, resp. 16, temp. 103. Administered ol. camphorae 35 c.c. in 5 doses; about 1 qt. equal parts lime water and milk during the day; 40 c.c. arom. spt. ammon. in 5 doses; 450 c.c. sterile salt sol. per vein; 1/15 gr. strychnine sulph. per os; 10 c.c. white scour serum (P.D.); and frequent enemas. At 9 p.m. attitude was slightly improved.

Seventh day no improvement, slight serous discharge from eyes, treatment about as on the sixth.

Eighth day, purulent discharge from eyes. Pulse 64, resp. 28, temp. 101.6, moribund condition, death at 12.30 p.m., about three weeks old.

*Clinical Diagnosis.* Acute gastro-intestinal catarrh with a marked congestion, or inflammation of the stomach revealed by the redness of the oral mucosa.

*Autopsy.* The abomasum was greatly distended and contained a large amount of a yellowish-green semi-liquid mass. Within the mass was one tangled ball of hay about the size of a man's fist, in addition to which was considerable hay scattered through the contents. The mucosa was highly reddened. Masses of hay and straw were found in a greenish semi-fluid mass in the rumen. A semi-solid greenish mass resembling clay was found in the caecum. The serous and mucous coats of the intestines were congested, especially those of ileum. Contents of small intestines slimy; of rectum slimy, containing coagulated clumps. Umbilical cord apparently normal. Cultures from the liver, spleen, and blood remained sterile. A pure culture of *B. coli* was found in the abomasum, rumen, and small intestine. When the autopsy was reported to the owner he recalled that the calf had eaten freely of hay when quite young.

The eating of hay, straw, and shavings by sucklings is not an infrequent habit. According to our available clinical reports it usually results in dysentery, and it is commonly described under this heading. In cases like the above it would seem appropriate to regard this condition as primarily

that of a foreign body in the stomach to which all other functional and anatomical changes are secondary. With this point in view an accurate clinical diagnosis would be more probable, and in this case the presence of a foreign body was actually suspected by Dr. Koenig.—*The Cornell Veterinarian*.

#### REPORT OF THE CIVIL VETERINARY DEPARTMENT, ASSAM, FOR THE YEAR 1917-18. [Abridged.]

During the year under report I continued to hold charge of the Civil Veterinary Department, Assam, and was on tour for 187 days, travelled 7156 miles by rail, 2296 miles by steamer, and 1334 miles by road.

The following hospitals and dispensaries were inspected by me :—

Shillong, Gauhati, Tezpur, and Dibrugarh three times; Silchar and Tinsukia twice each; Hailakandi, Karimganj, Patharkandi, Sylhet, Maulvi, Bazar, Habiganj, Dhubri, Goalpara, Bilashipara, Behali, Mangaldi, Nowgong, Sibsagar, Nazira, Jorhat, and Mariani once each. The cattle at the Upper Shillong Farm were twice inspected by me. In the districts outbreaks of contagious diseases were investigated and results of serum inoculation were checked as opportunity occurred.

I attended the camp of exercise at Dibrugarh and examined the candidates for Farriers' Certificates. I attended the Agricultural Show at Shillong and was one of the judges of live stock, also the Agricultural Conference held at Poona in December. As in previous years, I attended the Bengal Veterinary College as a member of the Board of Examiners.

In the Laboratory at headquarters 218 specimens were examined, of which 56 were found to be Anthrax, 28 Hemorrhagic septicæmia, and 9 Surra. In the previous year 128 specimens were examined.

#### Veterinary Instruction.

Twenty-four students attended the Bengal Veterinary College: they were distributed as follows :—

Class.	Stipendiaries: Government.		Local Board.	
	Students.	Passes.	Students.	Passes.
1st year	7	5	2	2
2nd year	7	5	—	—
3rd year	6	2	5	1
Total	20	12	4	3

There was only one private student in the 1st year class during 1917-18. He failed in the examination and was removed from the College.

#### Treatment of Diseases.

The total mortality as compared with the previous two years is as follows :—

	1915-16.	1916-17.	1917-18.
Equines	115	262	113
Bovines	41,104	44,952	55,354
Others	2,317	2,718	5,243
Total	43,536	47,932	60,710

These figures are furnished by the district officers and have been checked by the Veterinary Assistants as far as possible.

**EQUINES.**—*Anthrax*. There were 35 deaths reported from 7 districts. In the previous year 42 deaths were reported from 5 districts. Diagnosis was confirmed by microscopic examination in all districts.

*Surra*. Thirteen deaths were reported from this disease in 4 districts during the year, against 26 deaths in 5 districts in the previous year. Diagnosis was con-

firmed in all districts except the Garo Hills, from which no specimen was received for examination.

*Other contagious diseases*. There were 65 deaths from other contagious diseases against 192 in the previous year, but no details are available.

**BOVINES.**—*Rinderpest*. This disease was prevalent in all districts except the Naga Hills, and caused 29,808 deaths against 20,817 in the previous year. The heaviest mortality was reported from the district of Goalpara. Here few of the outbreaks were reported at the time of occurrence.

*Foot-and-mouth disease*. 5603 deaths have been reported from 9 districts against 5737 from 10 districts. It has been previously noted that few cattle actually die from the disease, but the sequelæ of the disease (poisoned and maggot-infested wounds) kill a considerable number.

*Hæmorrhagic Septicæmia*. There were 5525 deaths reported from 9 districts; in the previous year 4245 deaths from the same number of districts. Diagnosis was confirmed by microscopic examination in the districts of Cachar, Sylhet, Goalpara, Kamrup, Sibsagar, and Lakhimpur.

*Black-quarter*. This disease was reported from 4 districts and caused 483 deaths; in the previous year 241 deaths from the same number of districts were reported. No report of the prevalence of this disease was received from any of the districts during the year, and hence no reliance can be placed on the figures reported.

*Anthrax*. 2748 deaths were reported from 9 districts. In the previous year 1839 deaths were reported from 8 districts. Diagnosis was confirmed by microscopic examination in the districts of Cachar, Sylhet, Goalpara, Kamrup, Nowgong, Darrang, Sibsagar, and Lakhimpur.

From *other contagious diseases* 11,187 deaths were reported from 10 districts against 12,073 deaths from 9 districts in the previous year.

*Contagious diseases amongst other animals*. 5243 deaths were reported from 9 districts. In the previous year 2718 deaths were reported from the same number of districts. No information in detail is available regarding these diseases.

#### PREVENTIVE INOCULATION.

Inoculation was undertaken in 621 outbreaks of Rinderpest in 19 subdivisions. In these outbreaks 8956 animals died before inoculation; 38,295 animals were inoculated, of which 346 deaths were subsequently reported. In the previous year inoculation was undertaken in 348 outbreaks in the same number of subdivisions. In these outbreaks 9633 animals died before inoculation, and 29,986 were inoculated. There were 571 deaths reported amongst inoculated animals.

There was thus an increase of 8309 inoculations over that of the previous year.

*Anthrax*. 88 outbreaks of suspected Anthrax were reported, and the disease was definitely diagnosed by microscopic examination in 56 outbreaks.

Inoculation was performed in 60 outbreaks. In these outbreaks 18 equines, 638 bovines, and 4 others died before inoculation; 462 equines, 4504 bovines, and 184 others were inoculated, of which 18 bovines are reported to have died subsequently. In the previous year inoculation was performed in 46 outbreaks, in which 3814 animals were inoculated, of which 6 died subsequently from this disease.

*Hæmorrhagic Septicæmia*. 33 specimens from suspected cases were received at headquarters for microscopic examination. In 28 cases disease was confirmed. Inoculation was performed in 17 outbreaks in 11 subdivisions. In these outbreaks 157 bovines and 41 others died uninoculated, and 20 equines; 2092 bovines and 147 others were inoculated, of which 5 bovines are

reported to have died subsequently. In the previous year inoculation was undertaken in 13 outbreaks, in which 2216 animals were inoculated.

The total number of outbreaks where inoculation was undertaken during the year was 698, in which 9814 animals are reported to have died before inoculation. The total number of animals inoculated was 45,704, of which 369 animals died subsequently. In the previous year inoculation was carried out in 407 outbreaks, in which 10184 animals died before inoculation and 36,016 animals were inoculated, of which 578 subsequently died.

#### *Itinerant Assistants' work.*

The Assistants were 36 in number against 34 in the previous year. They visited 6685 villages and treated 10,562 animals for contagious diseases and 39,156 animals for non-contagious diseases. In the previous year 6729 villages were visited, 25,593 animals were treated for contagious diseases and 34,912 animals were treated for non-contagious diseases.

#### VETERINARY HOSPITALS.

*Gauhati Veterinary Hospital.* 170 equines, 634 bovines, and 237 others were treated as in and out-patients, making a total of 1041 against a total of 954 in the previous year. One equine and 35 bovines were treated in the hospital under the Cruelty to Animals Act.

*Silchar Veterinary Hospital.* 124 equines, 876 bovines and 167 others were treated in the hospital, making a total of 1167 against a total of 1478 in the previous year. The decrease is partly due to the demand for the services of Veterinary Assistants in the interior in connection with outbreaks of cattle diseases and partly to the transfer of assistants owing to unsatisfactory work.

*Shillong Veterinary Hospital.* During the year 1183 animals were treated as in and out-patients against a total of 1102 in the previous year. Fourteen bullocks were treated in the hospital under the Cruelty to Animals Act.

#### *Subordinate Establishment.*

The strength of the subordinate staff at the beginning of the year was 3 Inspectors and 32 Veterinary Assistants. During the year 4 new graduates joined the department, one Assistant reverted from, and one was deputed to, military duty, so that at the close of the year the total strength was 3 Inspectors and 36 Veterinary Assistants.

A brief summary of the work done by Veterinary Inspectors, the Staff and Reserve Veterinary Assistants is given below:—

Babu Satya Charan Mukherjee was in charge of the Dibrugarh Circle. He was on privilege leave for 1 month and 15 days and medical leave for 11 days during the year. He was on tour for 194 days and visited and revisited 183 villages and tea estates in connection with enquiries and investigations of outbreaks of diseases and inoculation results, etc. He inspected the Farm bullocks at the Government Agricultural Farm at Jorhat, and breeding bulls and municipal bullocks in various places in his circle. He travelled 2552 miles by rail, 2776 miles by steamer and country boat, and 946 miles by road. He inspected the work of the Assistants at Sibsagar, Nazira, Mariani, Dibrugarh, and Tinsukia 4 times each; Tezpur, Mangaldai, Jorhat, Golaghat and Badlipar 3 times each. Behali and North Lakhimpur twice each, and Kohima once.

Babu Guru Prasanna Sen was in charge of the Silchar Circle throughout the year. He was on tour for 157 days and travelled 2276 miles by rail, 1832 miles by road, and 382 miles by boat. He visited and revisited 116 villages and tea gardens in investigation of cattle disease. He inspected the work of the Assistants at Silchar, Karimganj, Patharkanki, and Habiganj 5 times

each; Hailakandi, Sylhet, Maulvi Bazar and Second Veterinary Assistant, Silchar, four times each, and Srimangal thrice.

Babu Srish Chandra Ghose was in charge of the Gauhati Circle throughout the year, and he also held charge of Dibrugarh Circle during the absence on leave of the permanent incumbent. He was on tour for 149 days, visited 118 villages and tea estates in connection with outbreaks, etc. He travelled 2990 miles by rail, 606 miles by steamer and 1491 miles by road.

He inspected the work of Dhubri, Bilashipara, Gauhati, Nalbari Barpeta and Nowgong four times each; Goalpara three times, and Shillong twice during the year under report. During the year he inspected the Upper Shillong Farm. The breeding bulls in his circle were inspected by him. While at headquarters he assisted in the Laboratory and Hospital work.

Babu Bhudhar Chandra Chatterjee was the Staff Assistant during the year. He has been on privilege leave for three months from 16th March, 1918, Babu Hem Chandra Sen, Veterinary Assistant, Shillong, officiated in his place. His duties were the same as in previous years—receiving, despatching, and keeping accounts of Sera and stock of inoculation outfits, etc., in assisting in the Laboratory, and attending in and out-patients at the hospital.

The names of the following Assistants are noted for the interest and care they have taken in their professional work during the year:—Staff Veterinary Assistant Babu Bhudhar Chandra Chatterjee, Veterinary Assistants Babu Hem Chandra Sen, Shillong and Maulvi Syed Ataul Haque, Mariani.

#### *General Remarks.*

The following Veterinary Inspectors are mentioned as having carried out their duties in a satisfactory and competent manner:—Babu Guru Prasanna Sen, Veterinary Inspector, Silchar Circle, and Babu Srish Chandra Ghose, Veterinary Inspector, Gauhati Circle.

There has been a further increase in the number of cases of Anthrax. This is not surprising considering the common procedure in the disposal of carcasses. These are left often where they die, to be devoured by vultures and jackals, and consequently the soil becomes heavily infected. It cannot be too strongly stated that in all cases of sudden death the carcass should be buried deeply without skinning it or cutting it in any way.

The question of sending a number of Assistants to the College annually for a course of post-graduate training will have to be considered. Most of the Assistants are in isolated posts where they have little or no opportunity to keep their professional work up to date, and where they are inclined to forget much which is essential.

During the year the "Manual of Cattle-diseases" in India, by Col. Walker, C.I.E., was translated into Assamese, and a limited number of copies were distributed.

Five Assistants from this Department are still serving with the Army Veterinary Corps. The Head Clerk and Third Clerk left temporarily to join the Military Accounts Department. Babu Basanta Kumar Chakrabarty was placed in charge, and the work has been carried out efficiently and satisfactorily.

W. HARRIS,  
Supt., Civil Vety. Dept., Assam.

Why do breeders persist in calling the breed "Holstein Friesian"? The Holstein cattle are red-and-white, and of a different type altogether. The Friesian cattle derive their name from the Dutch province of Friesland, not far from East Frisia, which is in Germany.—*Live Stock Journal.*

## ANTHRAX.

The following is from the Annual Report of the Chief Veterinary Officer, Board of Agriculture, for 1917.

"During the calendar year reports were received in relation to 2229 suspected outbreaks, of which 423 were confirmed by tests for diagnosis at the Laboratory—201 in England and 222 in Scotland.

The number and species of animals affected were?—cattle 451, horses 3, sheep 3, pigs 28: total 485, or 1·15 animals per outbreaks.

The disease occurred twice on 17 premises and 3 times on 4 premises. That is to say, in 25 outbreaks on 21 premises disease may have arisen from a previous case in the same year. In all, 80 outbreaks (18·9 per cent.) occurred on premises on which anthrax was known to have occurred in former years. The number of premises on which disease occurred during the year was 398.

With regard to the 343 outbreaks which occurred on previously clean premises, inquiries pointed to the following being the probable source of origin:—

- |   |     |
|---|-----|
| 1. Effluent from tanyards or other industrial undertakings getting into streams ... | 2   |
| 2. Feeding of infected carcase offal to pigs, etc. ...                              | 1   |
| 3. Use of imported feeding stuffs ...   | 203 |
| 4. Use of artificial manures of animal origin on the land ...                       | 34  |
| 5. Use of both imported feeding stuffs and artificial manures ...                   | 49  |
| 6. A recent death, not reported, but not improbably anthrax ...                     | 10  |
| 7. No explanation obtainable ...  | 44  |

In 26 cases the disease was found to exist in carcases which had reached slaughterhouses or knackers' premises, and, in an additional 46 cases, the deceased animals had been bled, opened, or dressed before the disease was diagnosed, the total number of carcases involved being 73. That means that, approximately, 15 per cent. of the animals affected with this dangerous disease were not reported as affected until their carcases were caught, as it were, at knackers' yards or slaughterhouses. This is very unsatisfactory and calls for firm action by Local Authorities when cases are brought to light. Eight human beings developed anthrax, one of whom appeared to have contracted the disease whilst handling affected pigs with a view to examining their throats: the others probably became infected as a result of slaughtering affected animals or cutting affected carcases.

The number of outbreaks which occurred in Scotland during the year was larger than the number which occurred in England. The incidence of disease in the counties of Banffshire and Aberdeenshire which has been previously commented upon, decreased from 40 per cent. in 1915 to 26 per cent. in 1916, respectively, of the Scottish outbreaks, and fell further during 1917 to 18 per cent. In Scotland, Lanarkshire contributed the largest number of outbreaks, viz., 16 per cent. of the total.

## The Medical Council and General Education.

At a meeting of the General Medical Council on Tuesday, Nov. 8th, at its offices, Hallam Street, W., Sir David MacAlister, the President, remarked upon the progress made by the English Board of Education with the elaboration of its scheme for a general school examination to take the place of multiple examinations in general education with which teachers and scholars have too long been burdened. The four Scottish Universities had received from His Majesty in Council a new Ordinance which establishes a common Entrance Board, empowered to accept the leaving certificate of the Scotch Education Department as the normal quali-

cation for admission to the universities in all faculties. This would liberate the Faculty of Medicine from the obligation, hitherto imposed upon it by Ordinance, to accept a lower standard of preliminary education than that required for degrees in arts and science. "I am," he said, "sanguine enough to believe that the so-called 'Junior' Preliminary Examinations for students of medicine will cease to be recognised in Scotland before they are extinct elsewhere." The large and indeed embarrassing affluence of students much below the age of 18 who were now entering the medical schools made the change more than ever expedient on educational grounds.

He also called attention to the remarkable Memorandum on Medical Education in England, addressed to the Board of Education by Sir George Newman, setting forth the changes that have gradually been made in the duties and responsibilities of the medical practitioner with reference to public health and public administration, and the grounds for requiring that a corresponding change should be made in the manner and matter of his training for their fulfilment.—*The Lancet*.

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

Walter Ackroyd, Halifax	£1 1 0
O. S. Broadhurst, Capt. R.A.V.C.	1 1 0
H. E. A. Charles, Lieut. R.A.V.C.	1 1 0
H. Cooper, Lieut. R.A.V.C.	1 1 0
W. W. Lang, Capt. R.A.V.C.	1 1 0
F. W. H. Smith, Bd. of Agric. (1914-18)	5 5 0
R. J. Stordy, D.S.O. Col. R.A.V.C.	1 1 0
C. Tracy, Capt. R.A.V.C.	1 1 0
A. J. Williams, Lt.-Col. R.A.V.C.	1 1 0
A. C. Wilson, Baskhamstead	1 1 0

Previously acknowledged: 1094 19 11

£2109 13 11

## ARMY VETERINARY SERVICE.

War Office, Nov. 29.

The following are among the Decorations and medals awarded by the Allied Powers at various dates to the British Forces for distinguished services rendered during the course of the campaign. The King has given unrestricted permission in all cases to wear the Decorations and medals in question:—

*Conferred by the King of Italy.*

ORDER OF THE CROWN OF ITALY.—OFFICER.

\* \* \* \*  
Lt.-Col. (temp. Col.) F. W. WILSON, C.M.G., F.R.C.V.S.

Extracts from *London Gazette*.

WAR OFFICE, WHITEHALL, Nov. 29.

REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Temp. Lt. to be temp. Capt.:—A. A. Hayman (Oct. 25).

Nov. 30.

Capt. A. S. Lawrie relinquishes the temp. rank of Maj. on ceasing to hold the appt. of Dep. Asst. Dir. of Vety. Servs. (Nov. 12).

Dec. 2.  
Capt. H. Chown is secd. for duty with Egyptian Army (Sept. 24).

**SOUTH AFRICAN VET. CORPS.**

Dec. 3.  
The following temp. Capts. relinquish their commns. on ceasing to be empld. with the Union Imperial Servs., and are granted the hon. rank of Capt.:—W. A. Dykins (Feb. 6); B. Van der Vijver (Feb. 20).

The following officer, who was a prisoner in Turkey, has been released:—Capt. H. Stephenson, M.C., R.A.V.C.

The following casualty is reported:—

DIED—Capt. P. Thexton, R.A.V.C.

**Flavour in Potatoes.**

The following notes appear on the leader page of the Dublin *Farmers' Gazette*. The only point which in any way connects up with veterinary practice is that, as with animals, it costs as much to rear the inferior article as it does to rear a good one. But just now it will appeal to a good many of us in view of the unsatisfactory quality of the table potatoes—landed on us, it is whispered, by some of the “wangling” of the food supplies by the Government.

“At a potato show held across the Channel, a few weeks ago, the winning dishes in order were of the following varieties:—Up-to-date, Prolific, Arran Chief, Stirling Castle, and Great Scot. The result, it appears to us, was based solely on the appearance of the tubers, a method open to the serious objection, that it furnishes no guide to flavour. Everyone admits that the “Date” is about one of the freest-cropping varieties grown, and none more profitable for raising either to market or to feed stock, but no one can claim for it that it has any merit in point of flavour to be regarded as a first-rate table potato. We do not believe that the variety deserves a statement that it is “unfit for human use,” but we are certainly strong on the point that it is absolutely flavourless, and does not appeal to the taste, as the Champion, or some of the old favourites. The verdict of the show referred to was that Midlothian Early as a first crop, British Queen as a mid-season crop, and the Date as a main variety, were all three sorts that could be commended for cultivation. We give full assent to the claims made for the two first-named varieties, but as a cooker for table use, the Date is about the last we would turn to.

Folks in this country are partial to a round-shaped potato; kidney-shaped sorts are not liked for the late crop. The three essentials insisted on in a variety are, that it boils well and evenly, has a firm flesh which becomes mealy when cooked, and, above all, possesses a distinct taste. Depth of eye, fineness of skin, colour of skin and flesh, and other points which are regarded as of importance by English growers are not given much heed to.

It is surprising to what extent potatoes enter into the daily diet of the people here compared with other countries. We are, without question, a great potato-eating people, and it is natural we should have developed a selective taste which will indicate varieties likely to command popular favour. It is on the table or on the plate rather than on the show bench, that a variety asserts its merits; if it pass this test, it can be assured a place in the potato field until something better supplants it.

**Personal.**

Ald. T. CHAMBERS, M.R.C.V.S., has just completed a very strenuous year as Mayor of Dudley. In that busy industrial town Mr. Chambers has carried on his profession for about forty years, and is well known in the Midlands not only as a Veterinary Surgeon but also in the hunting field. He rides to the Albrighton and Albrighton Woodland hounds, and some years ago was Master of a Local Drag Hunt. His Mayoralty of Dudley was a very popular one, and no Chief Magistrate of the ancient town has had a busier time. He had a great deal to do with the organisation of three very successful efforts for raising money for the war. The Tank “Julian” visited the town and well over a million pounds were deposited. Then followed a big scheme in the shape of a Market Sale to raise money for the Local Prisoners of War, with the result that the remarkable sum of £12,000 was raised. The Market Sale was opened by the Duke of Cornwall, and Ald. Chambers has very pleasant recollections of his association with His Royal Highness on that occasion. The third effort was “Feed the Guns,” and very considerably over a million was invested by people of Dudley and the locality. In his Mayoral social duties Ald. Chambers has been greatly assisted by Mrs. Chambers. One of the Alderman's sons, Frank, is a Major in the R.A.V.C. Another, Norman, a Lieut. in the Royal Naval Division, was wounded at the Dardanelles, and the third, Stanley, also joined the colours, and met with an accident whilst training. Amongst other things Ald. Chambers is a prominent Worcestershire Freemason: and years ago was attached to the Yeomanry, in connection with which he won many prizes.

**OBITUARY.**

THOMAS COOPER, M.R.C.V.S., Ribbleson, Preston.  
Graduated, Edin: April, 1873.  
Mr. Cooper died 15th November, aged 70 years.

P. THEXTON, M.R.C.V.S., Pontefract.  
L'pool: July, 1906.  
Death is reported whilst on army service.

**The late Mr. Robert McNae.**

Mr. McNae, of Rosemount, Maxwelltown, who was 71 years of age, had been in a poor state of health for a considerable time past. He was a native of Maxwelltown, and spent practically the whole of his professional life in the burgh, where, in addition to carrying on a large and ever-extending practice, he was able to devote much of his ability to public affairs. For over twenty-five years he was a member of Troqueer School Board, on which he rendered much valuable service, retiring only a year or two ago owing to the state of his health. He was also for many years one of the governors of Dumfries Savings Bank. A gentleman who stood high in his profession, of strict integrity and straightforward and genial disposition, he was followed in his retirement with the good wishes of a wide circle of friends, whose respect and esteem he enjoyed, and who will mourn his death. Mr. McNae is survived by his widow and two sons and two daughters.—*Scottish Farmer*.

### The outbreak of Rabies.

A Board of Agriculture enquiry into the rabies outbreak in Devon and Cornwall was held at Plymouth, the committee of investigation consisting of Lord Clinton, chairman, Mr. George Lambert, M.P., and Maj.-Gen. Sir David Bruce, R.A.M.C.

At the opening of the enquiry, Lord Clinton said that rabies could only have got a footing in this country by dogs being brought into it in defiance of the safeguards against disease provided by the Importation of Dogs Regulations.

The Chief Constable of Plymouth, in the course of his evidence, said that the first case came under the notice of the police on August 19th, Dr. Trelawny-Ross reporting that his dog had died under suspicious circumstances.

It had been denied that flying men took dogs across the Channel, but he was positive they did do so, and he thought the disease was brought to Plymouth from abroad. Canadians brought dogs across in the rush during the early part of the war. The public, generally, were conforming with the new regulations.

Supr. Chamings, County Police, said the earliest case of suspected rabies in the country area was reported on July 18th. It was the case of a heifer at Week Farm, Modbury, but rabies was not confirmed. It was not until September 9th that a case of rabies was confirmed at Modbury.

Evidence of the history of the outbreak in Cornwall as far as it could be ascertained, was given by the

Deputy Chief Constable, Mr. Banfield, the opinion being that it came from Plymouth.

Mr. Bloye, F.R.C.V.S., Plymouth, said that as far back as May there were some cases of dropped jaw in dogs in Plymouth, and these in the light of after events looked suspicious.

Replying to Mr. Lambert, witness said he could give instances of dogs having come to Plymouth by both air and sea. The one which came by air he destroyed, and one of the two which came by sea was traced.

Mr. Dunstan, M.R.C.V.S., Liskeard, criticised the Orders issued by the Board of Agriculture in this connection, and asked for something more stringent. He made several suggestions which were noted by the Committee. Power to shoot stray dogs at sight was one of his proposals.

Mr. R. Yeal, H.M. Customs representative, in reply to Lord Clinton, said that there had been a great congestion at the ports, and many dogs were on board ships. There was a possibility that some of the dogs might have landed without the knowledge of the Customs. He made a suggestion that no dog should be allowed on any ship without a licence.

Naval and military representatives spoke of the way in which the restriction orders were carried out at Plymouth. The War Office had issued to the troops abroad orders that no dogs were to be brought to this country. There had been one case of smuggling by a Canadian, and this was effectively followed up by the civil authorities.

It is stated that the latest police reports show that the disease is showing no signs of abating at present.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1588.

DECEMBER 14, 1918.

VOL. XXXI.

## RABIES

The report of the Board of Agriculture enquiry into the rabies outbreak, printed last week, contains nothing to surprise veterinary surgeons. It reveals a state of affairs which the profession generally believed to exist, but could not prove. It shows that the outbreak undoubtedly originated in dog-smuggling; that specific cases (which are not in the least likely to be the only ones) of dogs illicitly brought to England both by air and by sea are known to have occurred, and that in consequence the disease has assumed formidable proportions in two counties. All this we were prepared to hear; what concerns us now is how to deal with the position. The Board of Agriculture, though it may not be able to prevent some loss of human life, can be trusted to subdue the rabies already in the country in time; but what is to be done to prevent further importation of disease?

At the present moment, there is probably more danger of importing rabies than at any time during the war. There will certainly be still greater danger of this during next year. The most dangerous time will be when a general demobilisation begins. Then, unless a strict guard is kept, another re-infection of the country is almost certain. How is this to be prevented? We all know what ought to be done; the difficulty is how to do it effectively. Our existing regulations against the importation of rabies are sufficient, and the disease would never have reached us had these not been broken; the point now is to prevent further infringement.

Here the enquiry does not seem to help us much. One witness, a Customs official, suggested that no dog should be allowed on board any ship without a license; and this might aid in detecting dog-smuggling by sea. We are told, too, that the War Office has issued orders to the troops abroad that no dogs are to be brought to this country; but how serious an offence against military discipline is an infringement of this rule held to be? The existing civil penalties for dog-smuggling are altogether insufficient; for the maximum fine under the Act is far too light for an offence which, at present may cost human lives. Our most hopeful lines of action appear to be, (1) to instruct the public as far as possible as to the danger that exists, and, (2) to try to provide more adequate penalties for breaches of the regulations. The sentimentalists who strove so frantically to prevent us from stamping out rabies at the end of last century may again become very audible, and it is probably useless to argue with such people; but the recital of the history of our anti-rabies legislation should save the bulk of the nation from being misled by them.

## AN APPRECIATION OF THE A.V.S.

In a Supplement to the *London Gazette* dated 22nd November, 1918, His Excellency the Commander-in-Chief in India describes the work that has been carried on in India during the first three years of the War. Among other points, he calls attention to excellent work that has been done by the old Volunteer Force which has been reorganised into the Indian Defence Force. Amongst the eight names of this Force that he specially mentions for good services, we note that no less than three are members of the Indian Civil Veterinary Department; these officers are commanding three of the most important mounted units of the force. This large proportion of "mentions" is striking evidence of the capability of our members in filling positions which are outside their professional duties. All three officers were members of the Army Veterinary Department before joining the Indian Civil Veterinary Department.

## A SUGGESTED AGENCY.

The resolution of the Royal Counties Association which appears on p. 196 of this issue, suggests an entirely new departure. That ability to find at once, and with a minimum of trouble and expense, an assistant whose character and capability are guaranteed by the Council R.C.V.S., would, without question, be advantageous to many practitioners. Similarly, to the home coming junior, who is seeking such a position, to be at once placed with a capable, courteous practitioner, who is willing to pay the increased salary which present—and immediate future conditions demand, is a council as near perfection as is humanly possible. There are two views on the question which will require consideration before any definite step is taken in the matter. First there is the ability of the machinery at Red Lion Square to deal with additional work of this sort. It is—or should be, common knowledge that the stress of the last four years has increased the work there enormously—it is now as much as two men can handle effectively. An agency of the kind suggested—even as a temporary measure—would require a good deal of time and attention, and, without foreknowledge, would mean the collection and classification of information from all over the country; and it would entail a certain amount of unpopularity—if the work be done conscientiously. If it is to be a matter of labelling merely, the work would be less—and of less value to the men concerned.

Another matter for consideration is the present means of intercommunication between practitioners

and assistants. Under war conditions, many men have been glad to employ unqualified assistants who in other days would have none of them. A fair proportion of these men are "worth their salt" as assistants—some of them are practically never out of employment. But amongst them, as, indeed, among qualified assistants, there is considerable variety in character and in capacity. The channels by which demand and supply are transacted are various. Not a little is done by representatives of wholesale houses, who are in constant touch with the men. There are also established agencies, and there is frequently intercommunication between the men themselves. In either of these ways a certain amount of information is available which tends to the avoidance of "misfits."

The establishment of an agency at Red Lion Square will necessitate the building up of a card index on the usual lines, such as those in use in "Trade protection" offices.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### DERMO-EPIDERMIC SKIN-GRAFTING IN THE HORSE.

Levene, in 1917, reported an instructive case of this operation to the Central Society of Veterinary Medicine. The subject was a horse suffering from a large wound, irregularly triangular in shape, situated between the point of the right haunch and the hip joint. This wound was 20 centimetres long, 8 centimetres wide at its widest part, and an average of 3.5 centimetres elsewhere. This represented an ample wound surface, with considerable loss of substance. Although the wound had undergone various treatments for two months, it showed no tendency to cicatrise.

A skin-grafting operation was performed on August 3rd. Nine pieces of skin, taken from the thin skin of the flank on the same side, were grafted upon the wound by the following technique. The region from which the grafts were to be taken was shaved, and it and the wound were washed with ether. The first excavation, of from 8 to 11 millimetres in diameter, was then made with the knife between the fleshy granulations of the wound surface, its edges being formed by these granulations and its base by the aponeurotic or muscular surface of the wound. A skin graft, taken with a sharp knife and tooth forceps, was immediately deposited in this excavation, in which the blood was accumulating. This graft was from 6 to 8 millimetres in diameter, and was dermo-epidemic, being composed of epidermis and the major portion of the dermis. It was cut transversely to the dermis, and was bleeding when deposited in the excavation, as was also the latter. Once deposited in the excavation, the graft became fixed there by blood coagulation.

When all the nine grafts had been thus inserted, the wound was carefully covered with an aseptic protective covering, which was fixed to the skin

with collodion. This was removed eight times during the following month; and at each removal the wound was cleansed with compresses of sterile gauze soaked in warm sodium chloride solution of 5.75 per 1000 in strength, and a new and similar protective dressing was applied. At each removal a progressive diminution of the wound surface was observed, and finally, on September 3rd, the epidermal repair was complete.

By skin grafting Levene thus obtained (1) the cicatrization in 30 days of a wound which, for the two months preceding the operation, had shown itself absolutely refractory to treatment, and (2) a cicatrix which was flexible, and not adherent to the subjacent parts.—(*Revista de Higiene y Sanidad Pecuarias*).

##### A CASE OF TRICHINOSIS IN THE CAT.

Some years ago Ciurea reported a case of extensive trichinosis observed in Roumania in a cat fourteen years old. The animal was destroyed to prosecute parasitological investigations. The external surfaces of the superficial muscles presented numerous small whitish punctiform plates, situated between the muscular fasciculi, and some five millimetres distant from each other. They were perfectly visible to the naked eye, chiefly on account of the extreme thinness of the animal. The pillars of the diaphragm and the muscles of the thoracic and abdominal walls, on their internal aspects, presented the same alterations, which were also found in the depths of the different muscular masses. The viscera showed no lesions.

Microscopical examination showed that these formations, which at first were taken for sarcosporidia, were in fact encysted muscular trichinae. Their enveloping membranes were not yet completely calcified, and living larval trichinae could be demonstrated.

It appeared that the cat, when young, had been an excellent rat. It had probably, therefore, become infected through eating the flesh of trichinous rats.—(*Revista de Higiene y Sanidad Pecuarias*).

[There is not much in the literature concerning trichinosis in the cat; and this animal is not regarded as being very susceptible to infection.—*Transl.*]

##### THE CERUMINOUS GLANDS OF THE PIG AND CAT.

A. Mensa, having studied the ceruminous glands of the auditory passages in the pig and cat, communicated his results to the *Archivio Scientifico di Medicina Veterinaria* in 1914. The ceruminous glands are of two kinds, viz., (1) the tubular, which are analogous to the sudoriparous glands of the common integument, but adapted to the production of different material, and (2) the clustered glands, analogous to the cutaneous sebaceous glands, and with the same histological constitution. The numerical relation of the two varieties of glands varies according to the species of animal.

The tubular glands are absent in some of the mammalia: but both varieties are encountered in

the cat and the pig. In the cat they are in almost equal proportions, except as regards the size of elements. In the pig there is an evident numerical disproportion, the sebaceous glands being distinctly the more numerous.

For this reason, a uniformity of relations is observed in the cat which does not exist in the pig. The author finds that the glands in the cat are in corresponding series, the sebaceous glands being superposed to the tubular ones: one group of tubular glands corresponds to every group of sebaceous glands, and their relations of contiguity do not vary throughout. In a few instances there are exceptions to this rule, from absence or a lesser number of the tubular glands.

The sebaceous glands are always very well developed in the cat. The disposition of these glands corresponds to that of the analogous cutaneous glands. The tubular glands are of great extent and very ample. Their excretory canals, according to Lunghetti, constantly open into the hair follicles. Mensa, however, believes that in the majority of instances they open on the cutaneous surface, and less frequently in the hair follicles.

The characters described as pertaining to the ceruminous glands in the cat are also of general application to the glands in the pig; but there are some exceptions. In summarising these, Mensa says that the glands in the pig are very inferior to those of the cat in the number and in the extension of the glandular groups: nor are the glandular elements so well developed. The tubular glands in the pig are of less ample lumen and are less deeply situated than in the cat, in which animal they occupy the hypodermic connective zone bordering upon the perichondrium. In the pig, the presence of an adipose zone behind the tubular glands is noticed. In the pig, even more frequently than in the cat, the tubular glands open freely on the cutaneous surface.

The very debatable question of the genesis of the cerumen is connected with the existence of these two varieties of glands in the auditory passage. Mensa thinks that the sebaceous glands discharge the protective function of the passage and of the tympanic membrane, while the other glands only produce the yellow-grey pigment which imparts the colour to the cerumen, and also a liquid secretion which keeps the area of the external passage humid.—(*Revista de Higiene y Sanidad Pecuarias*).

#### SWINE FEVER.

[The following is the report of the Chief Vet. Officer B. of A. The brief note which we printed earlier (Oct. 26) is a summary of the information, but it is thought that many practitioners may prefer to have an opportunity to review the fuller evidence contained in the report.]

The number of suspected outbreaks reported in the statistical year 1917 was 10,261, and the number confirmed by combined inquiry in the field and at the Laboratory was 2104. This is a decrease of 2227 as compared with 1916.

The introduction of serum treatment and the organisation for its application as a policy were dealt with in the Annual Reports for 1915 and 1916.

A further report on the results of treatment is now submitted based upon records compiled by the Veterinary Department. The period extends from October, 1916, to Sept. 1917.

Certain records were also made of the outbreaks which occurred in the same period but in which serum was not administered, and the results in the serum and non-serum outbreaks, respectively are compared.

The number of outbreaks confirmed in the second twelve months of the serum treatment was 2531. Serum treatment was accepted in 1147 cases. Owners declined the treatment in 263. They preferred to slaughter for food immediately all healthy pigs in 322 instances. Conditions were unsuitable for treatment in 564 cases. No pigs remained alive on the premises for treatment at the completion of diagnosis in 220 outbreaks. Treatment was not offered in 15 cases.

The proportion of suitable cases (*i.e.*, cases in which it was not certain that infection had already spread to all the pigs) in which serum treatment was accepted was 80.5 per cent.

The total number of pigs involved in the 1147 serum cases was 42,504, an average of 37 pigs per herd, of which 31.2 per cent. died of swine fever, 1.2 per cent. died of other causes, 25.7 per cent. were killed for food, and 41.9 per cent. were freed at the end of the outbreak.

The 42,504 pigs consisted of 35,882 original stock, 676 moved on, and 5946 born during isolation. Of the original stock, 3553 (9.9 per cent.) were dead of the disease, and 713 (2 per cent.) were killed for food before treatment was adopted, the remaining 31,616 (88.1 per cent.) being isolated. In the previous year 1.3 per cent. fewer pigs were dead or were killed for diagnosis, but under the procedure then in force, and which ceased during the period, the Board slaughtered with compensation 4351 pigs (6.5 per cent.) *i.e.*, 15.1 per cent. of the stock had been disposed of by death or slaughter before treatment began in the previous year, compared with 9.9 per cent. for the period under review, when 6 per cent. more of the pigs were isolated. During isolation the number of pigs was increased 18 per cent. by birth and 2.1 per cent. by pigs being moved on to the infected premises, bringing the total number of pigs involved during isolation to 38,238, of which 24,952 (65.2 per cent.) were treated with serum, 8599 (22.5 per cent.) apparently healthy pigs were not treated for various reasons, and 4687 (12.3 per cent.) were already affected with swine fever.

Considered as a whole, the disposal of the pigs involved during isolation was as follows: 25.4 per cent. died of swine fever, 1.4 per cent. died from other causes, 26.6 per cent. were slaughtered for food, and 46.6 per cent. were freed.

The 38,238 pigs involved during isolation were composed of: (a) 3213 breeding pigs (8.4 per cent.) of which 436 (13.6 per cent.) died of swine fever, 11 (.3 per cent.) died of other causes, 804 (25 per cent.) were killed for food, and 1962 (61.1 per cent.) were freed; (b) 23,974 fattening pigs and stores (62.7 per cent.), of which 6479 (27 per cent.) died of swine fever, 165 (.7 per cent.) died of other causes, 8503 (35.5 per cent.) were killed for food, and 8827 (36.8 per cent.) were freed; (c) 11,051 suckers (28.9 per cent.), of which 2774 (25 per cent.) died of swine fever, 366 (3.3 per cent.) died of other causes, 877 (8 per cent.) were killed for food and 7034 (63.7 per cent.) were freed.

The following information has also been derived from records kept during the same period in connection with the 1384 outbreaks in which serum treatment was not applied. The total number of pigs involved in these outbreaks was 23,452, an average of 17 pigs per herd, of

which 10,121 (43·1 per cent.) died of swine fever, 9292 (39·6 per cent.) were killed for food, and 4039 (17·3 per cent.) were freed. These figures show increases of 11·9 per cent. and 13·9 per cent. in the death-rate and pigs killed for food respectively, and a decrease of 24·6 per cent. in the pigs freed, as compared with the figures for the serum-treated outbreaks. As the pigs known to have died from causes other than swine fever is less than 2 per cent. they have been included in the deaths from swine fever throughout the non-serum outbreaks. Of the 23,452 pigs, 21,585 were original stock, 1515 were born and 352 were moved on. Of the original stock 3674 (17 per cent.) died or were killed for diagnosis, and 364 (1·7 per cent.) were killed for food before isolation, the remaining 17,547 (81·3 per cent.) being isolated. The originally isolated stock was increased 8·6 per cent. by births (18 per cent. in serum outbreaks) and 2 per cent. by pigs being moved on, a total of 19,414 pigs being involved during isolation. Of these, 6447 (33·2 per cent.) died, 8928 (46 per cent.) were killed for food, and 4039 (20·8 per cent.) were freed. The records for this class of outbreak show that of the originally isolated stock 5639 (32·1 per cent.) were slaughtered for food during the first ten days of isolation in the non-serum outbreaks. The importance of this is that the death-rate from swine fever, though high, was kept down by slaughtering and salving the pigs exposed to infection, a useful method if the pigs are ripe and not breeding stock. It would appear also from the observations that a large number of affected pigs were killed for food. The 19,414 pigs involved during isolation comprised 1386 breeding pigs (7·2 per cent.) 14,787 fattening and stores (76·1 per cent.) and 3241 suckers (16·7 per cent.).

The proportion of breeding stock involved in untreated outbreaks was 1·2 per cent. less than in the serum outbreaks, and the pigs were accounted for thus:—Died 304 (21·9 per cent.), killed for food 609 (43·9 per cent.), freed 473 (34·2 per cent.), as compared with the breeding stock in serum outbreaks, there were increases of 8·3 per cent. and 18·9 per cent. in the death-rate and number of pigs killed for food respectively, and a decrease of 26·9 per cent. in the pigs freed.

The fattening of stores, which numbered 14,787, constituted a higher proportion of the isolated stock by 13·4 per cent. than in the serum outbreaks; 4656 (31·5 per cent.) died, 7937 (53·7 per cent.) were killed for food, and 2194 (14·8 per cent.) were freed. These figures, compared with the results in the serum outbreaks, are 4·5 per cent. and 18·2 per cent. higher as regards the death-rate and the number of pigs killed for food respectively, and lower by 22 per cent. as regards pigs freed.

Compared with the serum outbreaks, the proportion of suckers which, in untreated outbreaks numbered 3241, was 12·2 per cent. lower. These pigs were disposed of as follows:—By death 1487 (45·9 per cent.), by slaughter for food 382 (11·8 per cent.), by freedom 1372 (42·3 per cent.). These percentages are 20·9 and 3·8 per cent. higher as regards the death-rate and the number of pigs killed for food respectively, and 21·4 lower as regards the freed pigs in comparison with the serum outbreaks.

For convenience, suckers have been referred to under that title throughout this report, but all were not actually "suckers" throughout the isolation period.

*Scene: A Court in a Western State, U.S.A.*

*Prosecuting Attorney:* "Your honour, that bull-pup of yours has chewed up the court Bible."

*Magistrate:* "Well, make the witness kiss the bull-pup, then. We can't adjourn the court for a week just to hunt up a new Bible."

## ROYAL COUNTIES VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A.—SOUTHERN BRANCH.]

At the meeting on Friday last of the Royal Counties V.M.A., the President, Mr. J. Willett, proposed: "That the Royal Counties Veterinary Medical Association agree that a resolution should be forwarded to the Royal College of Veterinary Surgeons urging upon them the advisability of keeping a Register of Practices for Sale, Assistants wanting situations, also vacancies for assistants, whereby those members returning to civil life from the Army may have the opportunity of being placed in suitable employment, and that a small charge be made to cover expenses."

This resolution was unanimously agreed to by the members.

Dec. 11.

G. P. MALE, Hon. Sec. and Treas.

## ANNUAL REPORT OF THE VETERINARY DEPARTMENT, BRITISH EAST AFRICA, FOR THE YEAR ENDING 31ST MARCH, 1918. [Abridged].

The following constituted the staff of the Veterinary Department during the year 1916-17:—

*Chief Vety. Officer*—R. J. Sturdy.

*Dep. Chief Vety. Officer*—W. Kennedy.

*Vety. Pathologist*—R. E. Montgomery.

*Vety. Officers*—R. Edmondson, H. Brassey Edwards, F. J. McCall, O. Dixon, R. C. Wheeler, W. W. Henderson, G. N. Hall, F. J. S. Sheedy, A. W. Carter, T. C. Bradshaw, M. H. Reid.

*Assist. Vety. Pathologist*—W. Kearney.

*Indian V. Assists.*—Ghulam Hassan Shah, Khalilur Rahman Khan, Mohamed Ramzan.

A Permit Officer, two Clerks, three Live Stock Inspectors.

## DISEASES OF CATTLE.

*East Coast Fever.* Owing to the spread of East Coast Fever on the Uasin Gishu Plateau and the absence of many of the Settlers on active service, it has become necessary to modify the quarantine regulations in that district.

New rules are being drafted on this subject and it is hoped to publish these early next year.

The returns of the Government Analyst show that over one hundred dipping tanks are now in use. With the exception of a tank built by the military authorities at Athi River, no Government dipping tanks were erected during the year.

Considerable losses among cattle drawn from the Kitui district have occurred through the animals having to pass through the heavily infected area of Machakos on their way to Nairobi. The erection of a dipping tank in the neighbourhood of Machakos should considerably reduce this mortality.

The attention of all stock owners is again directed to the necessity of keeping careful records of the contents of dipping tanks, as several cases have come under notice, where, owing to want of proper supervision, the dipping fluids sent for analysis have shown enormous variations in strength. In the majority of these cases the trouble has been traceable to surface water gaining access to the tanks or to serious miscalculations in estimating the quantity of dip to be added.

The number of cattle, the property of Settlers, admitted to the East Coast Fever Testing area at Kamiti during the year was 264. The number of deaths was seven.

Dipping rules have been published which permit of freer cattle movement in the settled areas of the Protectorate than has been possible in the past.

During the year 984 dip samples were analysed as compared with 650 in 1915 and 480 in 1914.

The results of the analyses are as follows:—

Within 10 % of correct strength	percent 58.8
11 to 20 % above or below strength	22.3
Over 20 % above or below strength	18.9

**Trypanosomiasis.** The quarantine on the Thika district established in 1915, has now been confined to two farms. The measures adopted in dealing with this outbreak were briefly as follows:—"All infected farms were quarantined; microscopical examinations of the blood of all cattle in the area were carried out periodically; all infected animals were slaughtered and the owners were paid compensation." The number of animals found to be infected and destroyed was 249.

The trypanosomes found were of the Vivax and Dimorphon varieties, and the tsetse flies caught were *Glossina brevipalpis*, *G. longipennis*, and *G. pallidipes*. Only one specimen of each was found in 1½ years.

The bulk of the evidence goes to prove that infection in most cases occurred through the medium of tsetse flies in the neighbourhood of Ithanga Hills or at the outspan on the Saba-saba River on the Fort Hall road; but infected animals were found on a few farms where infection apparently could only have occurred between these farms and Thika Railway Station—a route which is tsetse-fly-free. Stomoxys may have been the transmitting agents in these cases.

**Anthrax.** Only a few outbreaks came under notice in the settled areas during the year. These occurred in the Nairobi and Kisumu districts.

**Pleuro-pneumonia** has spread considerably in the Masai Reserve and two outbreaks have occurred on Europeans' farms.

The spread of the disease in the Reserve has resulted from the movement of large numbers of slaughter oxen purchased for the Military authorities, and one outbreak on a European's farm was traceable to the same source. The other outbreak was apparently traceable to the introduction of cattle brought from a farm adjacent to the Masai boundary.

Infected animals were found in the vicinity of Ngong Station, and as these cases were a menace to the European-owned cattle in the neighbourhood, it was decided to slaughter off the infected animals and all in-contacts. The same procedure was adopted in the cases of the outbreaks on European farms.

Veterinary surveys are being carried out in the Masai Reserve with a view to ascertaining the extent and distribution of the disease, and when these are completed, it is proposed to form quarantine camps and carry out inoculations. These operations will require a large staff, and it is doubtful if much can be done until the cessation of hostilities. Precautions have been taken to prevent the further spread of the disease from the Reserve by prohibiting the movement of cattle therefrom.

Pleuro-pneumonia has been very successfully dealt with in the Bechuanaland Protectorate and the Chief Veterinary Officer of that Protectorate (Mr. W. H. Chase) has been good enough to supply full details of the methods adopted there. These details will be of great assistance in dealing with the disease in the Masai Reserve, when a staff is available.

**Contagious Abortion of Cattle.** A circular was issued by the Veterinary Department in January to all Farmers' Associations with a view to ascertaining the extent and distribution of contagious abortion. The information obtained in reply to this circular has proved of considerable value. It appears certain that this disease is widespread in most of the native reserves of the Protectorate and has been known to the natives for generations past. Although the disease usually pursues a mild course in native cattle, stockowners are

again warned of the serious results which are likely to follow if it is introduced amongst grade stock.

A pamphlet on this disease was issued by the Veterinary Department towards the end of the year and it is hoped that the information and advice contained therein will material assist stockowners in preventing or eradicating the disease.

**RINDERPEST.** During the year outbreaks of this disease have occurred in 13 districts.

When the staff was available the disease was suppressed by the double inoculation method. In February the settlers' and certain squatters' cattle were double inoculated in the Lumbwa, Muhoroni, Fort Ternan and Songhor districts. In all, 7917 cattle were inoculated, including 2450 squatters' cattle. The deaths numbered 172, of these 29 deaths are reported to have been due to Anaplasmosis, 9 to Red water and the remainder to Rinderpest. In many instances the squatters on the farms in these districts refused to have their cattle inoculated.

During the early part of the year several outbreaks of rinderpest occurred in the Nakuru district which were promptly eradicated by the use of serum. Two months later a second outbreak occurred which was dealt with in a similar manner. Three months later four outbreaks occurred simultaneously at distances of fifteen miles apart.

There is abundant evidence to show that this outbreak was directly due to the game, as buffalo, eland, reedbuck, and bushbuck were all found dead of this disease. It was decided to undertake double inoculation of the whole district, and I am glad to report that the measures taken were most effective and that the disease disappeared entirely after the inoculation. Approximately 14,500 cattle were inoculated with the simultaneous method of blood and serum and 12,000 in addition received serum only.

Great difficulty was experienced in ascertaining the precise losses in connection with the double inoculation but the Veterinary Officer in charge reports that deaths directly due to double inoculation were ½ per cent. and 2 per cent. of animals aborted.

An outbreak at Ravine in native cattle was eradicated by serum inoculation and 2256 cattle were inoculated.

The Civil Authorities of the Union of South Africa were notified of the spread of rinderpest in German East Africa towards the northern borders of Rhodesia.

The Veterinary Laboratory at Kabete have made the following issues of anti-rinderpest serum during the year:—

Civil	...	104,098 doses.
Military	...	215,000 "
Nyassaland	...	30,240 "
(On hand)	...	(47,762 ")
Total	...	397,602 "

Serum manufactured during the year	266,096 doses.
Balance on hand from last year	131,506 "

Total ... 397,602

**Blackquarter.** Outbreaks in cattle were reported during the year at Elmenteita, Nakuru, Muhoroni, Gilgil, and in Native Reserves at Nyeri, Meru, and Machakos.

At the Government Farm, Kabete, 721 cattle were vaccinated without mortality.

#### EQUINES.

**Epizootic Lymphangitis.** Several cases occurred in and around Nairobi, and one case at Fort Hall. Treatment with Potassium iodide has proved successful in many cases, but owing to the war the cost of this drug has

greatly increased with the result that, in many cases, the treatment is not carried on for a sufficient length of time to ensure a cure.

*Ulcerative Lymphangitis.* Cases have frequently come under notice throughout the Protectorate.

Although the causal organism is ubiquitous and the disease was in consequence deleted from the list of notifiable diseases under the Diseases of Animals Ordinance, it was found that, as soon as the quarantine restrictions were relaxed, many owners of horses and mules ceased to treat infected animals with the result that many animals were found in work with discharging sores all over their bodies. These animals were considered to be a source of danger to healthy animals, so it has been decided to make this disease notifiable once more.

*Horse Sickness.* The past year has been a particularly bad one for horse sickness, and districts hitherto known to be free from this disease have been visited by the epizootic.

**SHEEP AND GOAT.** As in former years the principal diseases of the sheep and goat which came under notice were Sheep and Goat Scab, Nairobi Sheep Disease, contagious foot rot, verminous gastro-enteritis, and contagious pleuro-pneumonia of the goat.

Owing to the difficulty experienced by many sheep farmers in eradicating sheep scab from their flocks a pamphlet on sheep dipping and the eradication of sheep scab has been written and will be published early next year by the Veterinary Department.

*Meat Inspection.* The following are the Nairobi Slaughterhouse returns for the past financial year, together with the three preceding years:—

		Bullocks.	Sheep.	Pigs.
1917-18	Slaughtered	3014	23,390	540
	Condemned	74	84	nil
1914-15	Slaughtered	2291	35,332	160
1915-16	"	4749	30,965	337
1916-17	"	3014	23,390	540

A new slaughter-house for pigs has been erected during the year and the inspection of pigs is much more satisfactory.

*Trade Stock.* During the year no outbreaks of disease were noticed among the trade stock arriving at Rumuruti from Northern Frontier District, Boran, Somaliland and Abyssinia. The following statistics are given of animals passing through the quarantine:—Cattle 3358, Sheep and goats 405, Horses 211, Mules 701.

The revenue collected from inoculation fees was Rs. 9323.

The figures show a great decrease compared with 1915-16 in cattle, sheep and goats, but an increase in horses and mules.

*Fort Ternan Quarantine Boma.* During the year 5062 trade cattle from Uganda and the Native Reserves bordering Lake Nyanza, and 5838 military oxen passed through the quarantine boma. All these cattle were double inoculated against rinderpest.

400 cattle were inoculated against blackquarter and 1500 oxen were dipped.

The revenue accruing from inoculation and dipping fees and sale of serum, etc., was Rs. 5253/10.

The number of brands registered under the Registration of Brands Ordinance during the year 1916-17 was 36: transferred 2: cancelled 1.

#### THE PERMIT SYSTEM.

Under the Diseases of Animals Dipping Rules (1916), permits will be granted for cattle which have been dipped for a period of two months at three-day intervals in a standardised dipping fluid to move from an East Coast Fever infected area to a clean area, provided that the animals can enter the clean area within 72 hours of their last dipping.

Permit Issuers will, before granting such permits, ascertain from the District Veterinary Officer or from the Chief Veterinary Officer, Nairobi, if the dipping fluid used for the dipping of the cattle has been regularly tested and kept at standard strength.

The thanks of the Department are due to those gentlemen who have acted as Permit Issuers during the year.

During the year under review practically the whole Veterinary Staff was employed on military duty but, as opportunity offered, every endeavour was made to deal with outbreaks of contagious diseases.

R. J. STORDY, Chief Vety. Officer.

#### The Life-Histories of the Lower Bacteria.

The following contribution to the question of the mutations of bacteria appeared in a letter to the Editor of *The Lancet* some months ago.

"The morphological modifications which appear in *B. typhosus* and some other bacteria, when subjected to particular environments, were studied by W. Murray and myself in 1902 and 1903 in the Gordon Laboratory of Experimental Pathology at Guy's Hospital, and I continued to give a good deal of attention to the subject here during several subsequent years. I am familiar with the 'aberrant' forms described by Dr. Hort. In a short paper published in this Journal (July, 1904), Murray and I drew particular attention to the following forms among those which we had noted: (1) Long unsegmented filaments, (2) filaments with segmentation at one end or in some part of their length, (3) beaded forms (presenting deeply staining beads at intervals along their length), (4) coccoid forms, (5) giant forms, (6) felted networks of filaments, (7) branching filaments.

Somewhat similar results were obtained (with *B. typhosus* and *Vib. cholerae*) by quite different methods by Professor Almquist of Stockholm, who published, in the same year, an account of them.

Murray and I concluded our own description with the following statement:—

"We are not at present prepared to estimate the precise importance of the foregoing observations. . . . But we conclude that the form in which we ordinarily see the *Bacillus typhosus* and some other bacteria in the laboratory is not the only form in which they may appear. Perhaps it may not even be the form in which by preference they exist as saprophytes. Further experiments which are now in progress suggest the possibility of an unsuspected complexity in the life-history of these micro-organisms. . . .

Some of the results of my further experiments were demonstrated in the Pathological Museum of the Oxford meeting of the Association in the summer of 1904, including appearances suggestive of "budding," oval and spherical forms, and the presence of tiny highly motile forms which I called 'dots.' But I have hitherto been unable to convince myself that I had evidence of a complete life-history, or to find a satisfactory method of securing permanent and demonstrable preparations of certain phases. Of this, however, I am certain: that any one who is interested in the matter can easily obtain filamentous forms of *B. typhosus* (and some other members of the typhoid-colon group) which show branching and the formation of lateral buds, by following the methods which Murray and I employed. I have repeated the experiment successfully since the appearance of Dr. Hort's important paper, and it seems probable that what I called 'dots' in 1904 may correspond to his filter-passing forms.

May one venture to dissent from the view expressed in your leading article, which seems to regard the evidence for the existence in this group of bacteria of forms small enough to pass through a piece of porcelain as of greater ultimate importance in pathology than would be the complete elucidation of their general morphology? Such a view is not only open to misinterpretation as a disparagement of a great part of Dr. Hort's work, but it seems to stand in striking conflict with the Euclidean doctrine that of necessity "the whole is greater than its part."—I am, et.,

Oxford, May 29.

E. W. AINLEY WALKER.

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918 :—

Dir. of Vet. Servs.—Col. F. Eassie, C.M.G., D.S.O., from Dep. Dir. of Vety. Servs., and to be temp. Brig.-Gen. (without the pay or allowances of that rank) while so employed (Oct. 12).

The following casualty is reported :—

WOUNDED—Capt. N. V. James, R.A.V.C., attd. R.F.A.

Extract from Sixth Supplement to *The London Gazette*.

WAR OFFICE, WHITEHALL, Nov. 26.

The following despatch from His Excellency the Commander-in-Chief in India on the work of the Army in India and of the Civil Departments of the Government of India and of Civilians in connection with the War has been received from the Government of India :

\* \* \* \*

9. At the outbreak of war, several Volunteer units undertook to replace or supplement, for as long as might be necessary, the Regulars in certain garrisons, in which employment they rendered excellent service. The Volunteer Force, as formerly constituted, has since ceased to exist and has been reorganised as the Indian Defence Force. The passing of the Indian Defence Force Act in 1917, rendered military training compulsory for all European British subjects in India between the ages of 16 and 50, thus bringing their military obligations more into line with those required of their fellow citizens in other portions of the Empire. These increased obligations have been accepted in a soldierly and patriotic spirit, and officers and men have spared no effort to improve their military training. The efforts made to develop and improve this force have been attended with success and, though only recently constituted, it has attained considerable efficiency.

16. A list of those whose services have been of particular value, and whose assistance and work I desire to bring specially to notice, forms the subject of Appendix I. of this despatch.

I have the honour to be, Sir, your most obedient servant,

C. C. MUNRO, General,  
Commander-in-Chief in India.

The following names appear amongst many others :

BLINKINSOP, Maj.-Gen. L. J., D.S.O., British Service.

EVANS, Lieut.-Col. G. H., C.I.E., A.D.C.,

Indian Defence Force.

PEASE, Lieut.-Col. H. T., C.I.E., V.D.,

Indian Defence Force.

WALKER, Lieut.-Col. G. K., C.I.E., F.R.C.V.S.,

Indian Defence Force.

## Milk yields of Goats.

A number of tests have been carried out by the Danish Goat-breeding Committee for the purpose of ascertaining what is the milk yield of goats in that country. A summary of the results is given in the *Journal of the Department of Agriculture* a few months ago.

In all 33 goats were tested, and included 12 representatives of the native Danish breed, 16 of the Saanen or Swiss type, 1 of the Norwegian type, and 4 cross-bred goats. The goats selected for experiment were located in different parts of the country; they were not chosen for any special excellence. The tests were carried out and records kept exactly as in the case of dairy cows.

The result of the tests was as follows :—The Danish goats gave an average yield of 1100 lb. The best goat, a strong six-year-old, gave 1510 lb, and the worst 659 lb. The average fat percentage was 4.1. The Saanen goats gave on an average 1230 lb. The best, a large and powerful animal, six years old, gave 1880 lb, and the worst 686 lb. Fat percentage 4.0. The Norwegian goat gave 992 lb milk, and the cross-breds 976 on an average. The fat percentage was 4.1 both in the case of the Norwegian goat and the cross-breds.

The results were regarded as satisfactory. The outlay on food was generally small, and the goats provided their owners with a nice little surplus in money at the end of the season, in some cases amounting to between £4 and £5. On the basis of these tests, it is calculated that, for the whole of Denmark, the average milk yield of goats is about 794 lb per annum. The Saanen goats are undoubtedly the best milkers on the whole, but they require more care and attention than the native breed, being generally of more delicate build, and having a thinner coat of hair. Accordingly, the native breed is recommended in cases where special care and attention cannot be given.

## Personal.

MACCANN.—November 20th, at Charleville Parade, Tullamore, the wife of J. S. MacCann, M.R.C.V.S.—twins (son and daughter).

Mr. W. S. KING, M.R.C.V.S., M.B.O., the well-known East London Veterinary Surgeon, has been unanimously elected for the third successive year to the Chair of the Central London Branch of the National Master Farriers' Association. Our readers will remember Mr. King's name in connection with very successful subscription lists for the V.V.B. Fund and the A.V.C. Comforts Fund.

## OBITUARY.

ALBAN BULL, M.R.C.V.S., Hook Norton, Oxfordshire.  
 Graduated, Lond: Dec. 1861.

Mr. Bull died 6th December, aged 80 years.

PATRICK McDONNELL, M.R.C.V.S., Market Sq., Dundalk,  
 Dublin: July, 1910.

Death occurred 21st October, at the age of 30.

RICHARD SAM REYNOLDS, M.R.C.V.S., Knotty Ash,  
 Liverpool. Lond: April, 1862.

Mr. Reynolds' death occurred on Monday last, 9th inst., at the age of 77. He served as member of Council R.C.V.S. 1887-94. He was for many years veterinary superintendent of the Liverpool Corporation, and was one of the founders of the Shire Horse Society and the Royal Lancashire Agricultural Society. He was one of the best judges of draught horses in the kingdom.

AUGUSTUS PHILIP PRESTON, M.R.C.V.S.

Dublin: July, 1917.

Mr. Preston's death occurred at his residence, Mallow, Co. Cork, on Monday, Dec. 2nd. He was the son of Mr. James Preston, F.R.C.V.S., Mallow, one of the best known and most respected veterinary surgeons in the South of Ireland, and had already given promise of following in the steps of his father, socially and professionally.

JAMES BLAKEWAY, jun., M.R.C.V.S., Major R.A.V.C., Red Hill, Stourbridge. Lond: July, 1894.

Major Blakeway died from Influenza, at a Military Hospital in Paris, on the 4th Dec., aged 36 years.

GEORGE EDWARD NASH, M.R.C.V.S., Richmond, Yorks.  
 New Edin: July, 1880.

E. MEASURES CHATTERTON, M.R.C.V.S., East Rudham.  
 Lond: Nov., 1908.

## DEMOBILISATION OF THE R.A.V.C.

To the Editor, "The Veterinary Record."

Sir,—I see from the public press that several doctors have already been released from the R.A.M.C. for return to civil life.

Is it not about time that those in the R.A.V.C. with practices and employments to go to, are released?

When is the R.C.V.S. going to wake up in this matter?

Yours, etc., "DISGUSTED."

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1589

DECEMBER 21, 1918.

VOL. XXXI.

## TRANSITION.

The question of when veterinary surgeons are to be released from the Army is already beginning to be asked, and seems rather premature. General demobilisation can hardly be expected for several months at least, and possibly may be much later. We know that a great number of Army horses are to be sold during the next three months; the fact that this will lessen the work of the R.A.V.C. and increase the need for civil practitioners at home is not likely to escape the notice of the Government. There is evidence that the whole question of the release of veterinary surgeons is under consideration at Red Lion Square; and we may be sure that the only veterinary body likely to have any influence with the Government will do its best to secure fair treatment for veterinary surgeons and to ensure that the profession shall reach its maximum of utility to the nation; but at present, while a "state of war" still exists and is likely to continue for some time, that must remain the first consideration.

It is quite uncertain what the permanent after-war strength of our Army will be; but it seems more than possible that it may be considerably above the pre-war status. In any case, there will be not a few vacancies, by the release of the older officers who would normally have retired during the last four years. It follows, then, that a number of our younger members at present holding temporary commissions will be offered permanent ones. Speaking broadly, it may be said that any young member who gets the chance of permanent enrolment in the R.A.V.C. will do well to think carefully before refusing it. Its acceptance means a settled career, with a fair pension assured at its termination.

The present prospects of civil practice are much more dubious. There is a difficult and uncertain time before the whole of the nation's workers; and the conditions are likely to be especially unstable during the next ten or twelve years—that is, during just the period in which the young member of to-day might have expected to establish his position in normal times. Moreover, the period will be in some measure a transition one for veterinary surgeons; and, though some of the changes we may expect will increase the profession's utility, they may not tend to its financial advantage.

Another feature calls for immediate attention. We have seen that our Council has made repeated efforts to obtain the release of veterinary students who are serving with the colours, but so far with little success, and with less sympathy from the War Office authorities. That this is a necessary provision for the near future is obvious, and that it

is recognised in the scheme of demobilization is evidenced by the provisions announced in the public press, portions of which are reprinted on another page of this issue. It is an open secret, too, that the number of students now remaining in the Colleges is hardly sufficient to justify their existence.

## ROYAL ARMY VETERINARY CORPS.

We have to congratulate our confrères in the Army Veterinary Service on the honour that has been done them in the raising of the Army Veterinary Corps to the status of a "Royal" Corps.

It is a fitting testimony to the good work that has been performed by this Corps in all theatres of the war. When we consider the small staff which existed when the war started we must realise that the foundation of the magnificent structure which so quickly sprang up must have been very soundly laid. The nucleus corps was evidently well trained and thoroughly efficient.

## THE SERUM OF LECLAINCHE AND VALLÉE.

Leclainche and Vallée, in *La Presse Médicale* of April 2, 1917, published a new communication upon the methods of using their polyvalent serum. Their account is based upon the very numerous applications of the serum which have been made in the course of the war; and they state that it may be employed by local applications upon infected surfaces and by subcutaneous injections when post-traumatic infections are present. The two methods of application are dealt with separately.

*Local applications.* The use of the serum excludes that of antiseptics, which, in addition to the coagulating and neutralising actions which some of them exercise, almost always have the disadvantage of depressing and paralysing the organic cells. This latter action is essentially antagonistic to that which the serum is desired to effect.

The serum must be brought into contact with the anatomical elements; and therefore it is necessary to free the wound from the various elements which cover it by a minute washing with boiled water.

The testimonies of medical men who have employed the serum on the prescribed lines are completely favourable. P. and L. Bazy write, "In wounds which cannot be completely united by sutures, we apply the polyvalent serum freely, obtaining excellent results. The healing processes are not painful, the flesh is well preserved, the lips of the wound remain admirably flexible, and very rapid granulation commences at its base." On the

other hand, Prof. Quénu, summarising the results of various surgeons, decides that "the polyvalent serum causes a considerable diminution of suppuration." At the same time a greater activity in the epidermisation of the edges of the wound, a lessened sensitiveness, and an improvement of the general condition with descent of the temperature, are observed. These conclusions are applicable both to war wounds and those which result from the opening of phlegmons, anthrax lesions, etc.

It is recognised, however, that "discrimination is necessary in the treatment of septic wounds, and that it is sometimes desirable not to perpetuate the same formula of treatment." It is known to-day, for instance, that the *bacillus pyocyaneus*, which is often resistant to the polyvalent serum, yields marvellously to a weak solution of nitrate of silver.

Cazin and Mdle. Krongold say, "When the beneficial action of the polyvalent serum, locally applied, does not manifest itself rapidly and evidently, it is useless to continue this treatment." In these circumstances the microbial flora of the wound include at least one microbe that is not comprised among the numerous forms used for obtaining the serum. It follows from this that the polyvalence of the serum is always being improved by the introduction of microbial types isolated from war wounds.

*Subcutaneous injection.* In the hands of Prof. Lagneu, Cazin, Vautrin, Gosset, Berger and Bergeron, Prof. Delbet, and Prof. Quénu, who have studied its employment, the polyvalent serum has shown itself a very valuable agent against infections and toxic complications of large wounds. Cazin concludes from his experience that in particularly serious cases in which he has had recourse to the serum the results have been very favourable, for he has observed a progressive and sufficiently rapid descent of the temperature with an improvement in the general condition. And Quénu adds, "It is impossible to deny that sero-therapy has contributed much to the treatment of gravely affected septicæmic patients." It appears to be as an anti-streptococcic agent that the serum acts in circumstances.

The hypodermic use of the serum (either alone or in conjunction with local treatment by means of the serum or some other agent) is also very valuable in the prevention of operative complications following operations in infected ground.

Prof. Delbet uses the serum in doses of 30 c.c. daily in polymicrobial infections. He says that in certain cases high doses appear to him to have a notable action, and his impression is that that they have saved the lives of some patients.

Hypodermic injections of this serum entail no danger of seric or anaphylactic accidents. The conclusions of the Academy of medicine, etc., are completely assuring on this point.

Leclainche and Vallée manufacture their serum at the laboratories of the Alfort Veterinary School, and hitherto it has been used solely for the necessities of the war. It is well, however, to follow its present evolution; for in time of peace it will be of great utility, and will then be available to all the world.—(*Revista de Higiene y Sanidad Pecuarias*).

#### THE TREATMENT OF EQUINE TETANUS WITH ANTI-TETANIC SERUM.

H. Bergh contributed his experience of this subject to *The Journal of the American Veterinary Medical Association* for 1916. The conviction that anti-tetanus serum is of little or no value in the treatment of equine tetanus seems general among veterinarians. The author's experience is very different; and he has as much faith in the curative efficacy of the serum as in its preventive efficacy.

The author especially insists upon the necessity of using sufficiently high doses of the serum. Doses of from 500 to 1500 units\* are absolutely insufficient as curatives; and their use as such, even in the initial stage of tetanus, inevitably involves failure. For prophylaxy, however, 1500 units suffice, and the preventive injection should not be neglected in any case of a suspicious wound; for with this the tetanic infection is avoided with almost absolute certainty. The treatment of tetanus with serum is costly, on account of the quantity required; and the veterinarian ought to make this clear to the owner before commencing treatment.

In treating equine tetanus the author does not limit himself to the use of serum alone, but employs every means to augment the resistance of the animal. At the point of infection, if it is possible to find it, he employs energetic disinfectants—cauterisation and incision, or extirpation of injured tissues. He does not exclude the use of suitable medicines, but always administers them subcutaneously, endo-venously, or intra-rachidially, and never by the mouth. He also insists upon the advantage of keeping horses in a dark and silent stable, and placing cotton-wool in their ears, in order to prevent the spasms as far as possible. The injection of the serum is generally subcutaneous, and only in the graver cases endo-venous. The author usually injects 9000 units daily, divided into three doses of 3000 units each. He maintains this quantity for four days, and then lowers the doses, injecting 1500 units three times daily.

In the course of the last six years seventeen cases of equine tetanus have come under the author's observation. Twelve of these recovered perfectly under treatment with serum, conducted as above stated. One horse died after receiving 15,000 units of serum, and another after receiving 24,000 units. In the other three cases the owners refused to bear the cost of serum treatment; and all three terminated in death.

The following are two of the author's cases:—

A racehorse, with a nail in the foot, was found by the author to have the limb rigid, and showed the whole appearance of tetanus. The same morning 3000 units of serum was injected; the dose was repeated at midday and in the evening, and so on for four consecutive days. The wound was treated with carbolic acid, glycerine, and distilled water, and covered with iodoform gauze and bandaged. The dressing was changed every day. On the fifth day of treatment the dose was reduced to 4500 units in the day, and continued at this rate for four days

\* U.I. in the original.

more. Then for another four days 3000 units daily, divided into two doses, were given; and finally 1000 units daily, also divided into two daily doses, were given for two days more. The horse in the meantime recovered completely, and within a month was able to run again.

The second case was a horse suffering from tetanus, with very accentuated trismus. The animal was put in a dark, quiet stable with a good straw bed; and one grain of arecoline, and half a grain of atropine were administered. Treatment with serum, on the same lines as in the preceding case was then instituted; and arecoline and atropine were also given twice daily. After three days of treatment the trismus gradually disappeared, the horse commenced to eat, and in a short time recovery was complete. Altogether this horse received 60,000 units of serum.

W. R. C.

#### SUCCESSFUL TREATMENT OF PURPURA IN THE HORSE WITH THE DANISH POLYVALENT SERUM PREPARED BY JENSEN. Prof. Dr. E. FROHNER.

There are two dark points in "petechial fever," the etiology and the treatment. Here as in other infectious diseases an efficient treatment depends on an accurate investigation of the cause. Apparently it is an affection having a polybacterial origin, since the streptococcus of strangles, the etiological agent in contagious pleuro-pneumonia, ordinary pyogenic bacteria and perhaps other as yet unknown infectious agents may under certain conditions induce a hæmorrhagic pathogenic effect that induces the characteristic clinical picture of purpura. With this multiplicity of causes it is conceivable that a single method of medicinal treatment is not sufficient for all cases and forms of the disease. For this reason the iodine and silver therapy, as well as the monovalent serum therapy in the form of antistreptococcic serum have not met with general support.

A new era in the treatment of purpura seems to have dawned since Professor Jensen in Copenhagen developed a polyvalent serum against the disease. The serum is prepared by the intravenous injection of various streptococci isolated from animals affected with purpura. This serum is then mixed with that used for strangles. The administration is per vein. On the first day 200 c.c. are injected. This is repeated once or twice in 100 c.c. doses according to the severity of the disease and the tendency to recur.

After using the serum in his clinic for about a year, Prof. Froehner concludes that it is undoubtedly a specific, that in many cases it has a very direct and rapid effect. Twelve cases were treated, nine of which recovered.

The visible effect of the serum is as follows:—

1. The petechiæ on the nasal mucous membranes usually disappear in 24 hours.
2. The swelling of the skin and the intestinal hæmorrhage (colic, prolapse of the rectum) likewise promptly disappear.
3. The temperature drops. The hyperleucocy-

tosis which is specially unfavourable in purpura rapidly returns to normal.

4. The serum should be administered. In two cases when given four to six days too late the horses died.

It costs about \$9.00 a litre.—*Monatsheft für praktische Tierheilkund.* Bd. 25 (1913) S. 61.

To the Editor of "The Veterinary Record."

#### DEMobilISATION.

Sir,—Members of the Profession now on Active Service will have noticed in the press the following announcement with regard to Demobilisation:—

"Officers or men serving in the Forces who in civil life practised a profession . . . . can secure their registration for demobilisation most rapidly by filling up the Civil Employment Form which all Members of the Forces can obtain from their Commanding Officers."

With a view to rendering any assistance that may be possible during the period of demobilisation, I have been authorised to open a Register to contain the following information:—

1. Names and addresses of Veterinary Surgeons requiring qualified Assistants.
2. Names and addresses of Veterinary Surgeons seeking appointments as Assistants.
3. Names and addresses of Veterinary Surgeons desiring to dispose of a practice or of entering into a partnership.
4. Names and addresses of Veterinary Surgeons desiring to purchase a practice or to enter into partnership.

I shall be glad, therefore, to receive from Members in civil life such particulars as will be useful to Members seeking an assistantship or wishing to purchase or enter into partnership; and from Veterinary Officers about to demobilise such information regarding themselves and their desires, as would be useful for inclusion in the proposed Register.

The Register will, of course, be open to inspection by Members at this office, and it will be possible, I hope, to supply extracts from it in due course, to enquiring Members of both classes.

I am, Sir, your obedient Servant,  
FRED BULLOCK, Secretary.

#### DEMobilIZATION.

RELEASE OF MEN WITH DEFINITE EMPLOYMENT.

##### EMPLOYERS' PROCEDURE.

The Controller-General of the Department of Demobilization and Resettlement makes the following announcement:—

2. . . . . As it may now be possible to release men from the Forces more rapidly and sooner than was at first anticipated, the Government desires to accelerate the process of identifying the men in the Forces, who,

though they cannot be treated as pivotal, have definite work awaiting them.

3. The Government have therefore decided to afford the opportunity to employers of securing, by direct communication with their employees in the Forces in the manner explained below, that those who were in their employment on or before August 4, 1914, and to whom they can now offer employment, shall be registered for demobilization. Such a definite offer of employment in writing, if produced to his commanding officer by the officer or man concerned, will be accepted as evidence that employment is awaiting him, and the man will be registered by his commanding officer to be demobilised in the same way as a "slip man" under the Civil Employment Form procedure and ranking for priority after a "pivotal" man.

#### FORM OF EMPLOYER'S OFFER.

4. The offer must be in the following form:—

*I/we (full name and postal address of employer) hereby declare that (full name and naval or military number and address of employee) was in my/our employment before August 4, 1914, and that I/we are prepared to offer him employment as a (name and occupation) immediately on his return to civil life (or give the date after which the employment will be available).*

5. The offer must first be taken or sent, in the case of officers to the local district director of the Appointments Department; in the case of other ranks to the local advisory committee attached to the nearest Employment Exchange, who, without guaranteeing in any way the offer of employment, will do their best to eliminate spurious or collusive offers. The district director of the local advisory committee, where they are in a position to endorse the offer, will forward it to the officer or man at the address given by the employer, but will assume no responsibility for the correctness of the address.

6. If the officer or man desires to accept the employment offered, he will hand the statement to his commanding officer, who will then register him for demobilization.

7. This procedure is additional to—(1) the selection of pivotal men now in progress; and (2) the use of the Civil Employment Form, which is now being filled up by members of the Forces, and the postcards (A.D. 406) and R.C.V. forms, which employers have been invited to fill up.

8. The actual date of demobilization will depend partly on naval and military exigencies, and partly on the transport and other accommodation available; but no other formalities will be required. . . . It will be understood that some individuals are so essential to the Forces that they cannot be released immediately; for example, the *personnel* of military railways overseas, hospital attendants, farriers, mechanical transport, and officers or men in the Regular Army serving on pre-war attestations.

11. It is not necessary for offers of employment to be sent to officers or men in the following classes:—

- (b) Officers and men who have notified their commanding officers that their civil occupation is that of a student or teacher and are accordingly classified in Industrial Group 43 in their naval and military documents. Instructions as to the demobilization of such individuals are being sent to the Forces.
- (c) Officers or men serving in the Forces who in civil life practise a profession or are their own employers, such as barristers or proprietors of one-man businesses, can secure their registration for demobilization most rapidly by filling up the Civil Employment Form which all members of the Forces can obtain from their commanding officers.

#### MEN OVER 41.

The demobilization of men over 41 who were called up early this year under the Military Service Act No. 2, 1918, has been ordered.

The number of men demobilised grows daily. The figures up to Friday, 13th inst., were:—Prisoners of war, 75,000; Miners, 25,000; Shipbuilders, 1000; Miscellaneous, 11,000; Sick and wounded, 35,000; Pivotal men, several thousands.

Maj.-General Burnett-Hitchcock, D.S.O. (the Director-General of Demobilization), indicated four main points which have to be considered in demobilizing—the situation, the rate of demobilization, its extent, and "how to be demobilized." Having remarked on the necessity of an army of occupation in Germany, he said that Mesopotamia, Palestine, the Black Sea region, the Dobrudja, and the Indian frontier had also to be remembered; and it was very difficult to keep units up to strength in some of these places on account of transport, malaria and other diseases. People were apt to overlook everything but the occupation of Germany. The machinery of demobilization was started in this country months ago, but however ready we might be on this side, the Army in France could not be prepared at a moment's notice. There were 17,000 units in the Army, and nearly every unit possessed some peculiarity. The term of service, for instance, varied to an extraordinary extent, 19 different categories of soldiers had some peculiar statutory right to be safeguarded, and the demobilizing authorities must see that all such rights were kept in mind.

#### GOVERNMENT GRANTS.

The Controller-General of the Department of Demobilisation and Resettlement of the Ministry of Labour makes the following announcement:—

#### HIGHER EDUCATION AND TRAINING FOR THOSE WHO HAVE SERVED IN THE FORCES.

In order, so far as possible, to restore the supply of men of higher general, scientific, professional, and business attainments whom the nation needs for every profession and industry, the Government have decided in suitable cases to provide financial assistance for ex-Service men who desire to resume suitable education and training, with a view to their re-settlement in civil life, but who cannot otherwise afford to meet the expenses involved. The scheme sanctioned applies equally to officers, warrant officers, non-commissioned officers and men in the ranks, provided they are of suitable educational promise.

The facilities available for the types of training contemplated are limited, and assistance can therefore only be granted up to the limit of these facilities to those candidates who can satisfy the authorities charged with the administration of the scheme, and the bodies or persons by whom the training will be given, that they are of sufficient educational promise to justify a grant being made to them from public funds.

The amount of the assistance to be granted will be separately determined in each case. On the one hand, this amount will be limited to the actual sum deemed sufficient to meet the necessary fees and the expenses of maintenance of the candidate, after due account has been taken of his private means, if any; of any scholarships to which he may be entitled; and of the assistance which can reasonably be expected from those who would, in ordinary circumstances, have borne or contributed to the expenses of his training. On the other

hand, it is intended that the amount of the assistance shall be such as will enable a candidate to take his course of training under reasonably adequate conditions, even though he or his friends are not in a position to meet any part of the expenses of the course.

In the case of those candidates who were married before the date of the armistice, November 11th, 1918, an allowance may also be made towards the maintenance of children up to and including the age of 15.

Assistance may be granted for :—

1. Courses of higher education in institutions approved by the Board of Education or by the Board of Agriculture and Fisheries, as the case may be, or by the corresponding departments in Scotland or Ireland.

2. Such practical training in offices and works and professional employments as may be approved by the Ministry of Labour.

3. Such practical training on farms, &c., as may be approved by the Board of Agriculture and Fisheries, or by the corresponding Department for Scotland or Ireland.

Officers and men now serving with any unit in H.M. Forces, whether at home or abroad, will, before being demobilised, receive through the naval or military authorities concerned the appropriate forms of application for assistance—in the case of the Army and Royal Air Force, Army Form, Z. 15. The completion of these forms will be sufficient in itself to ensure that the candidate's case will be taken up for further inquiry and due consideration. Applicants (whether serving in or discharged from the Forces) who fail to receive Army Form Z. 15 or Navy Form S. 1299 should apply, on or after January 13, 1919, for the necessary form to the appropriate District Directorate of the Appointments Department of the Ministry of Labour (the Department charged with re-settlement in civil life of officers and men of like educational qualifications), according to their respective places of residence.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918 :—

Michael Cunningham, Capt. R.A.V.C.	£1	1	0
A. E. Darwell, Leigh	1	1	0
J. R. McCall, Maj. R.A.V.C. (1918-19)	2	2	0
E. McSwiney, Cork	1	1	0
Previously acknowledged	1119	1	11
	£1124	6	11

#### ARMY VETERINARY SERVICE

B.M. 2709/3/18 (V.D.)

To :

Directors of Veterinary Services.

**All Expeditionary Forces.**

Deputy Directors of Veterinary Services.

Assistant Directors of Veterinary Services.

**All Home Commands.**

On the publication of the Royal Warrant granting the distinction of "Royal" to the Army Veterinary Corps the following memorandum dated War Office, 28th November, 1918, has been received from Lieut.-General Sir John S. Cowans, G.C.M.G., K.C.B., M.V.O.,

Quartermaster-General to the Forces, and is circulated for information of all ranks and publication in the Orders of Royal Army Veterinary Corps units :—

"The Director-General,

"Army Veterinary Service.

"On the occasion of His Majesty the King being graciously pleased to raise the Army Veterinary Corps to the status of a 'Royal' Corps, the Quartermaster-General to the Forces wishes to convey to all ranks his congratulations and appreciation of the good work which they have performed during the present war.

"The Corps by its initiative and scientific methods has placed Military Veterinary Organization on a higher plane. The high standard which it has maintained at Home and throughout all the theatres has resulted in a reduction of animal wastage, an increased mobility of Mounted Units and a mitigation of animal suffering unapproached in any previous military operations."

L. J. BLENKINSOP, Major-General,  
Director-General, A.V.S.

War Office, 29th November, 1918.

EXTRACTS FROM *London Gazette*,

WAR OFFICE, WHITEHALL, Dec. 12.

REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Temp. Qrmr. and Lieut. H. Lloyd, R.A.V.C., to be Capt. under Art. 330, R. Wt. for pay and promotion (Nov. 9).

Dec. 17.

Temp. Lt. to be temp. Capt. :—P. F. Wilson (Nov. 22).

TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Dec. 12.

Capt. M. T. Sadler relinquishes his commn. on acct. of ill-health, and retains the rank of Capt. (Dec. 13).

#### Ophthalmia among Horses in France.

At a meeting of the War Emergency Committee of the Royal Agricultural Society of England, held on Wednesday, 12th inst., under the chairmanship of Sir John H. Thorold, the following resolution was passed :—

"That the War Emergency Committee desires to call the attention of the War Office to the grave danger attending the repatriation of Army horses from France owing to the prevalence of a malignant form of ophthalmia, and from other infectious diseases in a more or less epidemic form among these horses. It is hoped that special care will be taken to safeguard the interests of horse-owners and live stock breeders in the United Kingdom."

#### Qualification for practice in U.S.A.

[The following particulars were printed in the "Announcement of the New York State Veterinary College, 1915-16," at Cornell University, Ithaca, and were accompanied by an official notice that from September, 1916, all students who register in the Veterinary College will be required to take a four years' course in order to receive the degree of D.V.M.]

The number of British graduates who practise in the States is not large, and the subject is therefore not of immediate importance; but the standpoint in the granting of the license differs from our own. Quite recently our Council had before it the draft of an Ordinance for South Africa, which also differed from our methods. It appears likely that our own governance will require alteration from time to time to meet changing conditions; and the methods of other men is worth attention.]

Legal requirements for license to practise veterinary medicine and surgery in the State of New York. Extracts from Article X, chapter 860, Laws of New York, 1895.

§ 171. **Qualifications for Practice.** No person shall practise veterinary medicine after July one, eighteen hundred and ninety-five, unless previously registered and legally authorised, unless licensed by the Education Department and registered as required by this article, nor shall any person practise veterinary medicine who has ever been convicted of felony by any court, or whose authority to practise is suspended or revoked by the Education Department on recommendation of a State Board.

§ 176. **Admission to Examination.** The Education Department shall admit to examination any candidate who pays a fee of ten dollars and submits satisfactory evidence, verified by oath if required, that he (first) is more than twenty-one years of age; (second) is of good moral character; (third) has the general education required in all cases after July first, eighteen hundred and ninety-seven, preliminary to receiving a degree in veterinary medicine; (fourth) has studied veterinary medicine not less than three full years, including three satisfactory courses, in three different academic years, in a veterinary medical school registered as maintaining at the time a satisfactory standard; (fifth) has received a degree as veterinarian from some registered veterinary medical school. The degree in veterinary medicine shall not be conferred in this state before the candidate has filed with the institution conferring it, the certificate of the Education Department that three years before the date of the degree, or before or during his first year of veterinary medical study in this State, he has either graduated from a registered college or satisfactorily completed an academic course in a registered academy or high school; or has a preliminary education considered and accepted by the Education Department as fully equivalent.

§ 178. **Examinations and Reports.** Examination for license shall be given in at least four convenient places in this State, and at least four times annually, in accordance with the Education Department's rules, and shall be exclusively in writing and in English. Each examination shall be conducted by an Education Department's examiner, who shall not be one of the medical veterinary examiners. At the close of each examination, the Education Department examiner in charge shall deliver the questions and answer papers to the Board, or its duly authorised committee, and such Board without unnecessary delay, shall examine and mark the answers and transmit to the Education Department an official report, signed by its president and secretary stating the standing of each candidate in each branch, his general average, and whether the board recommends that a license be granted. Such report shall include the questions and answers, and shall be filed in the public records of the university. If a candidate fails on the first examination, he may, after not less than six months' further study, have a second examination without fee. If the failure is from illness or other cause satisfactory to the Education Department, they may waive the required six months' study.

§ 179. **Licenses.** On receiving from the State board an official report that the applicant has successfully passed an examination and is recommended for license, the Education Department shall issue to him, if in their judgment he is duly qualified therefor, a license to practise veterinary medicine. Every license shall be issued by the university under seal and shall be signed by each acting veterinary medical examiner of the board and by the officer of the university, who approved the credentials which admitted the candidate for examination, and shall state that the licensee has given

satisfactory evidence of fitness, as to age, character and preliminary and veterinary medical education and all other matters required by law, and that after full examination he has been found properly qualified to practise. Before any license is issued it shall be numbered and recorded in a book kept in the Education Department office and its number shall be noted in the license. This record shall be open to public inspection, and in all legal proceedings shall have the same weight as evidence that is given to a record of conveyance of land.

§ 180. **Registry.** Every licensee, to practise veterinary medicine, shall, before the licensee begins practice thereunder, be registered in a book to be known as the "Veterinary Medical Register," which shall be provided by and kept in the clerk's office of the county where such practice is to be carried on, with name, residence, place and date of birth, and source, number and date of his license to practise. Before registering, each licensee shall file, to be kept in a bound volume in the county clerk's office an affidavit of the above facts, and also that he is the person named in such license, and had, before receiving the same, complied with all requisites as to attendance, terms and amount of study and examination as required by law and the rules of the university as preliminary to the conferment thereof, and no money was paid for such license except the regular fees, paid by all applicants, therefor; that no fraud misrepresentation or mistake in any material regard was employed by any one or incurred, in order that such license should be conferred. Every license, or if lost, a copy thereof, legally certified so as to be admissible to evidence, or a duly attested transcript of the record of its conferment, shall before registering, be exhibited to the county clerk, who only in case it was issued or endorsed as a license under seal by the Regents, shall endorse or stamp on it the date and his name preceded by the words: "Registered as authority to practise veterinary medicine, in the Clerk's office of — county." The clerk shall thereupon give, to every veterinarian so registered a transcript of the entries in the register, with a certificate under seal that he has filed the prescribed affidavit. The licensee shall pay to the county clerk at total fee of one dollar for registration affidavit and certificate.

#### ANNUAL REPORT OF THE VETERINARY DEPARTMENT, BRITISH EAST AFRICA, FOR THE YEAR ENDING 31ST MARCH, 1918. [Abridged].

(Concluded from p. 198.)

#### EIGHTH ANNUAL REPORT OF THE VETERINARY PATHOLOGIST.

As in last year's report, I do not propose to touch on the Research work accomplished for this year, since that will be included in my comprehensive report, which I hope to have ready for publication very soon. Details of Personnel, Correspondence, Livestock and Routine work only are included.

**Personnel.** The Assistant Veterinary Pathologist, Capt. Kearney, proceeded on Home leave on Aug. 27th, 1916, his place being taken by Capt. Bradshaw, who commenced duty here on Aug. 8th, 1916.

**Laboratory Staff.** Mr. Schultz, who was attached to the Military in the field, returned to the laboratory on October 17th. Mr. E. W. Gray proceeded on short leave to South Africa on January 24th, 1917.

Mr. J. Ford remained on duty throughout the year.

Mr. H. Gray arrived on first appointment on Oct. 29, 1916.

Mr. J. Burton, Overseer, has been at the Laboratory throughout the year.

**Laboratory Students.** Mr. E. Bessler has been at the Laboratory throughout the year.

With reference to Laboratory students, desire to point out that there have been vacancies for three students

for the past three years, and since the departure of Messrs. Duirs and Hoddinott, in August, 1914, and February, 1915, respectively, one post only has been occupied.

This is regrettable in view of the excellent opportunity there exists for youngsters of the country to obtain a thorough knowledge of Animal Diseases that would fit them for a scientific career, or help them to become successful stock raisers in the country hereafter.

*Correspondence.* During the year 4407 inward and 4478 outward letters and telegrams have been dealt with, making a total of 8885.

One Staff Bungalow has been added to the Laboratory buildings during the year.

*Technical Work of the year.* In addition to the routine duties, a total of 2614 slides and specimens received from Government officials and stockowners were examined and reported on during the year, divided as follows:—

[The figures in brackets are the numbers reported "No parasites seen."]

Horses, 622 (346); Mules, 274 (154); Donkeys, 37 (17); Bovines, 1488 (675); Sheep, 5 (5); Goats, 3; Pigs, 12 (5); Dogs, 78 (43); Camels, 6 (3); Fowls 63 (32); Wild animals—Serval cat, 2 (2); Thompson's Gazelle, 3; Jackal, 1 (1). Insects and various Ticks, 19. Flies, 3.

*Serum and Vaccine Preparations.* 266,096 doses of anti-rinderpest serum were manufactured during the year—an increase of 61,616 doses over that for the last financial year.

The issues of rinderpest serum for the year are as follows:—

Civil Administration	doses	104,098
Military	"	215,502
Rinderpest Commission, Nyasaland	"	30,240
Leaving balance in hand	"	47,762

Again the Rinderpest Serum Suspense Account has been in operation throughout the year, and has been the means of allowing the manufacture of serum to continue on a sufficiently large scale to meet all the demands for serum.

Other sera and vaccines prepared and issued during the year are as follows:—

	Prepared.	Issued.
Blackquarter vaccine	10,400	13,720
Colon Bacillosis	2,072	1,748
Ulcerative Lymphangitis	323	300
Canine Trypanblau	456	309
Bovine Trypanblau	161	94

The number of doses of Blackquarter vaccine issued over the amount prepared was drawn from the balance in hand of last year. In conclusion, I again wish to express my thanks to all the members of the Laboratory Staff as well as to the Veterinary and Administrative Officers for their loyal co-operation during the year.

(Signed) W. KEARNEY,  
for R. E. MONTGOMERY,  
Vety. Pathologist.

#### SWINE FEVER.—THE ADMINISTRATION BY THE VETERINARY DEPT. OF THE BOARD OF AGRICULTURE.

To the Editor of "The Veterinary Record."

I have been on the point of writing on this subject on several occasions, but something has always cropped up to prevent me so doing. I should like to hear the views of the country practitioner (who is the backbone of the veterinary profession) on the matter.

I have a very extensive country practice, and I think I have held the confidence for a number of years of my

clients—amongst them some of the largest breeders of prize stock in England: yet, when a suspicious case of swine fever occurs on the farm, the Board of Agriculture send a veterinary practitioner some 30 or 40 miles motor journey to make the necessary examination. A friend of mine who has, I should say, one of the largest veterinary practices in England, informs me that his opponent in the town is appointed by the Board of Agriculture, and when a suspicious case of swine fever occurs amongst his clients' stocks this gentleman takes over the case, and that my friend is then not allowed to have anything whatever to do with the matter.

I consider this treatment by the Board of Agriculture is most unprofessional, degrading, and unfair. What is the use of taking the M.R.C.V.S. degree and passing a post-graduate course? Surely it does not require any special skill to kill a pig and send the intestines to London. Would the medical profession tolerate this? I was talking to my medical attendant on the subject, and he thought it scandalous.

I would suggest that the Board of Agriculture should supply all veterinary surgeons with the necessary forms, and when an owner of a pig suspects something wrong he should at once report to his veterinary surgeon, or, should he not have one, to the nearest, and let him carry out the Board of Agriculture's instructions. It could be done with expediency and at half or a quarter of the expense.

When the Tuberculosis Order was in vogue we had to put up with the same treatment. If a deputation of County Veterinary Surgeons were to wait on the President of the Board of Agriculture and state their views, I am of opinion that something might be done to remedy this unfair treatment.

"PLAYFAIR."

#### An enthusiast on the Suffolk.

The following excerpts are from a long letter in *Live Stock Journal*, over the signature "S."

"In France, wherever there was one, the Suffolk horse made a reputation. It was the pride of the unit, the pet of the men, the worker of all workers. Its kind nature made it the horse the men took to; and when it came to work it earned a reputation of an equine Hercules. I met one in the Umptieth Division, on the Somme; it was known as 'Baby'—a great, fine, typical gelding it was, too, noted for its intelligence. From the Colonel to the latest-joined driver, 'Baby' was the only horse that mattered. It pulled guns and gun teams, when stuck, out of shell holes; and its remarkable good nature, although the times were trying, if anything, increased as the time went on. The Somme mud, the cold, exposed horse lines, the misery of active service conditions in a sea of mud, made no difference to 'Baby's' health, who managed to keep 'wholly fat,' and just as fit as if he was in some well-known stud in England, sleeping on clean wheat straw instead of on the soft mud. 'Baby' was, in fact, like most Suffolks, a sound, extraordinarily healthy and fit creature, a born worker, with the heart of a lion when it came to pulling a load.

"The war tested us all, both man and the lower animals, and some stood it, some didn't. It was a test worthy of the name, and in this test the Suffolk horse, wherever he was, earned a reputation which officers and men who had a Suffolk horse in their unit will never forget. One and all, the representatives of the breed proved their superiority to any other heavy horse as a good-natured, hard-worker, with a love of pulling, which means so much in moments of anxiety."

"The old-fashioned, short-legged Suffolk Punch, in the writer's opinion, is the horse for work and sound health, and he believes that this type of animal will be the Suffolk, which everybody will be looking for after

the war. Unfortunately, breeders have tried to eliminate this type by breeding a chestnut, long-legged, Shire-like thing, without any hair on its legs, with the idea that a Suffolk like a Shire in looks would please our neighbour breeders. But now, no doubt, the real old Suffolk will now come into his own."

"Although the war has taken away many needed animals, and the shortness of food has added to the difficulties of horse breeders, the Suffolks to-day have many grand specimens amongst them. If anything, there is a marked increase in bone. A visit to some of the leading studs will show what the Suffolk horse can do in war time on a limited diet."

"Typically a farmer's horse, able to move heavy loads, and with work ingrained in its character, free from the hair which leads to leg troubles, and free from vice, it is only a question of time before the Suffolk will become still more in demand, for a horse of this type is needed everywhere; and there is no doubt whatever that money spent to-day in starting a breeding stud is well invested and will double itself in value, if the stock chosen is the right sort, and the outlay is tempered with discretion."

#### A Bacillus resembling the Tetanus Bacillus.

R. S. Adamson and D. W. Cutler, in *The Lancet* for 1917, describe an anaerobic bacillus identical morphologically with that of tetanus. This new organism is sometimes encountered in tetanic wounds, but is also found in other parts.

Cultivations of this microbe experimentally injected into rabbits and guinea-pigs do not produce tetanus; but this does not prove that the microbe causes no morbid alterations in septic wounds.

The organism belongs to the vast group which includes the *bacillus tetani*, the *b. oedematis maligni*, the *b. aerogenes capsulatus*, and probably also other species as yet ill defined. Its presence in septic wounds augments the already existing difficulties of diagnosing tetanus microscopically.

#### Organising Research.

A movement has been inaugurated by the National Farmers' Union, which, if wisely guided, may lead to the organisation and consolidation of the forces engaged in Research work connected with animal diseases. The Scottish Chamber of Agriculture has fallen into line at once, and no doubt, when its Science Committee has reported on the subject, the Highland and Agricultural Society will follow suit. So far a good deal of work is under weigh, and from time to time various reports have been published. There is just the possibility that such efforts, isolated and without co-operation, may leave us very little wiser than we were.

What is wanted is a central authority to control and direct all such work. Research into sheep diseases, for example, can never be conducted apart from a laboratory, but they can never be carried out in a laboratory. Only on disease-infected areas can braxy, looping-ill, and scrapie be investigated, and only in premises associated with navel-ill can adequate and satisfactory research be made into phases of that disease. A central authority could allocate to every man his own particular line of inquiry, and if endowed with sufficient funds, as it must be, only such an authority could adequately remunerate each investigator, and co-ordinate results. *The Scottish Farmer.*

VOL. XXXI.

## RECORDS.

Throughout the war period there has been a considerable diminution in our clinical records; and a large proportion of those that have appeared have come from the army. From the point of view of the civil practitioner desiring clinical reports directly bearing upon his own work, this is rather to be regretted. Of course there is much in army veterinary practice which has that bearing; but there is much also that has little or nothing of it, and on the whole the latter has formed the greater part of what has been published in English and foreign veterinary journals during the war.

Wound treatment has of course figured largely in our war literature, and some advances have been made in it; but some of them are not likely to prove very adaptable to general practice. As regards specific diseases, perhaps the three upon which most has been written are mange tetanus, and epizootic lymphangitis. Useful knowledge has been gained regarding the first; but here again some of the methods which have evolved, such as treatment by baths, will often be inapplicable in civil practice. The treatment of tetanus is always interesting, because generally so unsatisfactory; but it may fairly be said that every one of the new treatments the war has produced has yet to prove its efficacy. Moreover, we all know that there are some districts and many practices in which tetanus is seldom or never seen. Perhaps, of all these three diseases, the war has taught us most regarding epizootic lymphangitis; but the advances in connection with it are not likely to be very useful to practitioners in England. The disease is scheduled here; and, though we are likely enough to renew our acquaintance with it before long, our main concern will be with its diagnosis with a view to stamping out. Speaking generally, most of our army records are more scientifically interesting than directly useful to civil practitioners.

On the other hand, though the war has increased the range of civil practice, and fields of work formerly comparatively untrodden are now becoming familiar to us, little evidence of it has yet appeared in the journals. Neither have we seen much of old branches, such as bovine practice, which are more important now than ever before. Busy as practitioners have been during the war there are few records of their activity. Horses, cattle, sheep, pigs, rabbits, poultry!—we all know how comparatively rarely veterinary advice was once sought for most of these, and to-day it is constantly in request for all. The great bulk of the profession are behaving as they usually do—attending to their practices, and disregarding the duty of reporting their work for the common benefit.

## Royal College of Veterinary Surgeons.

### EXAMINATIONS IN LONDON.

At a meeting of the Board of Examiners, held in London on December 13th, 1918, for the Written, and on following days for the Oral and Practical Examinations, the following gentlemen passed their Final Examination:—

Mr. H. W. Brekke	Mr. H. C. P. King
I. R. R. Coleman	H. Thornton
L. N. Devenish	

The following passed their Third Examination:

Mr. A. Bakar	Mr. L. St. Bel Gollidge
J. E. Barnes *	H. Jerrom *
E. Beaumont	T. R. Thomas

The following passed their First Examination:

Mr. S. W. J. Van Rensburg	Mr. E. P. Ambrose
H. P. Standley	

### EXAMINATIONS IN EDINBURGH.

The following passed his Second Examination:

Mr. J. Lyon

The following passed their First Examination:

Mr. J. W. Kilmurry	Mr. T. J. Patterson
--------------------	---------------------

### LIVERPOOL V. SCHOOL.

The following passed their Final Examination:

Mr. H. Salusbury	Mr. A. Williams
------------------	-----------------

The following passed his Third Examination:

Mr. J. K. G. Sissons

### GLASGOW V. COLLEGE.

The following passed his Final Examination:

Mr. C. Macpherson

### EXAMINATIONS IN DUBLIN.

The following passed their Final Examination:

Mr. M. A. O'Connor	M. G. West
J. J. O'Donovan *	W. White

The following passed their Third Examination:

Mr. J. V. Carroll	Mr. J. J. Lyons
R. J. Condy	M. F. Murphy *
M. M. Conway	T. O'Carroll
C. A. Lister	L. R. Swift

The following passed their Second Examination:

Mr. J. M. Morris	Mr. C. McCloskey
T. F. Connolly	

The following passed their First Examination :

Mr. H. G. Dooley	Mr. H. L. McConnell
J. J. Gildea	P. McGlinchey
P. J. Nolan *	T. A. Mernagh
R. Gregg *	P. M. Quille

Marked thus \* passed with Second Class Honours.

### ROYAL COUNTIES VETERINARY MEDICAL ASSOCIATION.

[NATIONAL V.M.A.—SOUTHERN BRANCH.]

A General Meeting was held at 50 Friar Street, Reading, on Friday, December 6th, when Mr. J. Willett (the President) was in the chair, and there were also present Messrs. Coleman, Hancock, F. Willett, Parker, Verney, and the Hon. Secretary and Treasurer (Mr. G. P. Male).

Arising out of the minutes, the Hon. Sec. said the resolution they sent to the Board of Trade, *re* feeding, was acknowledged, and they said they had put it before the proper authority. As they knew, very soon afterwards the ration was altered, allowing an unlimited amount of straw to be given, which was a great advantage.

As to the resolutions passed at the last meeting *re* veterinary fees, he had forwarded these to the Secretary of the National Veterinary Association, and he hoped that Society would take steps to carry them out by bringing it before the various Government departments and Insurance Companies.

*Apologies for absence* were received from Professor Wooldridge, Major Rees-Mogg, Major Simpson, Messrs. MacCormack, E. Brown, McIntosh, Gillard, Hughes, and Baxter.

*Correspondence.* A letter was read from Mr. Donaldson Pottle urging the importance of increasing the scale of fees.

#### ELECTION OF OFFICERS.

The PRESIDENT said that now they had arrived at what they might term the Victory year, and he would like to propose a member for that Chair who he thought would receive the support of every member of the Association, and that was their Secretary, Mr. Male. (Applause). He would very much like Mr. Male to take on the work from now. He (Mr. Willett) had no ambition to go on with it. Mr. Male had done all the spade work. Considering the hospitality they had had there and the work he had done it was only proper they should elect him to that chair during Victory year.

Mr. COLEMAN said he would be very pleased to second that.

Mr. F. WILLETT supported the motion.

Mr. MALE said that their President had carried on so splendidly during these trying times when they had had small meetings, and had done such admirable work generally for the Association, that he felt now the war was over he should have a jolly good year, and that they would all meet in very different circumstances. He hoped Mr. Willett would carry on for another year. He had carried on right through to now, and it was only due to him that he should be asked to do so for another year.

Mr. WILLETT replied that that was not quite correct. The only member who had really carried on had been their Secretary and Treasurer, Mr. Male. He (Mr. Willett) had no ambition except to help over the rough times through which he had just passed. He had not spoken to Mr. Male about it, but he could promise him, on behalf of the Association, that he would have universal support.

Mr. COLEMAN said he would be delighted to still further the proposition. He appreciated the President's endeavours, and all the inconvenience he had been put to to carry on. ("Hear, hear"), but Mr. Male had made such an excellent Secretary that it would be showing their appreciation on that auspicious occasion if they made him their President.

Mr. MALE thanked them for their kind remarks which he said he was sure were not at all deserved. Under the circumstances he felt he must accept. The work had not been done as it should have been. Without the help of the Assistant Secretary, Mrs. Male, he could not have carried on. He had worked with the utmost cooperation with Mr. Willett, and they had to thank him more than he (Mr. Male)—("The President, No, no!")—for the work he had done during the past four years.

The proposal met with hearty and unanimous approval.

Mr. MALE proposed that the retiring Vice-Presidents (Messrs. Hancock, Broad, Parker, Verney and F. Willett) be re-elected, with exception that Mr. J. Willett take the place of Mr. Hancock, the retiring Vice-President.

This was seconded and agreed to.

The PRESIDENT thought Mr. Male ought to have someone to help with the Secretaryship. Would Mr. Coleman take on the Secretaryship for a year while Mr. Male was President?

Mr. COLEMAN: You won't ask me to take it on any longer?

The PRESIDENT then moved that Mr. Coleman be elected Secretary.

Mr. HANCOCK seconded, and the proposal was passed.

The HON. SEC. proposed that Mr. J. Willett be elected Treasurer.

Mr. VERNEY seconded, and it was agreed to.

#### VETERINARY FEES.

Mr. MALE said the question was put on the agenda, as he had letters from one or two members saying they were sorry they could not come down and discuss it. It seemed to him it was a question for veterinary surgeons in certain districts to agree among themselves to increase the fees. Fees varied so much in different districts that if they could come to some arrangement among themselves they would do more good than if it was left to the National Veterinary Medical Association. If they all agreed to increase the fees no one could get the work done any cheaper, and the clients would have to pay. With regard to shoeing they had had a meeting of the farriers in Reading and district, and had put up the prices from time to time and they had had no difficulty whatever.

The PRESIDENT mentioned that the fees charged in Glasgow for shoeing were 17/- for cart horses, 16/- for farm horses, 16/- for trotting vanners, and 10/- for cobs and ponies.

The HON. SEC. said that another reason why he put the resumed discussion on the agenda was so that members who had increased their fees 25 per cent., and had put it on their bills, could report whether there had been any trouble arising from that source. He had put it on his bills, but had not had one question asked. He saw in the Derbyshire list that there were special increases for individual cases—foaling, calving, cleansing, etc. If they charged 25 per cent. all round, that would bring the amounts up, practically, to what they were in Derbyshire. If they charged 25 per cent. on mileage, that brought it up to 1/3 a mile. He simply added 25 per cent. on the bottom of the bill, which included the increase on medicines and everything else.

Mr. COLEMAN said one charged more for short visits. He gave the items, but carried out no prices and put the sum total at the bottom. He had not had a single complaint.

The HON. SEC. pointed out that there was a great deal of difference in the fees charged for tuberculin testing, anti-abortion inoculation, intra-tracheal injection for husk, and milk fever injection.

The PRESIDENT: Can you suggest a price that should be charged? [Mr. Male said that on the Derbyshire list the minimum price was £1 1s. He did not know whether that was for one animal or a number.] (Several members: For one).

Mr. VERNEY said that they had added 10/6 after the first, he believed.

The HON. SEC. did not think they could fairly charge £1 1s. each for a large number of animals. He did 17/ one night not long ago, and did 76 two nights ago. He thought that if 5/- a head was charged that was a reasonable price for a large number, if the journeys were charged in addition. A guinea or a guinea-and-a-half and the journey was reasonable for a single case. As to anti-abortion injection the Board gave the material, and it was really sent out for the benefit of farmers, and was not for veterinary surgeons to make a big profit out of it. Viewing it from that light he had charged reduced fees where there was a large number of animals. He generally worked in a number of farms at the same time. As to intratracheal injection for husk the price would have to vary with the number of animals. If a few animals, one would have to charge 5/- a head. If there were from 30 to 40, 1/6 to 2/6 would be sufficient.

Mr. F. WILLETT asked what should be the charge for tuberculin test in the case of four or five cows.

Mr. MALE: 10/- a head.

Mr. F. WILLETT said he charged £1 1s. for the first, 10/6 the next two, and 5/- each after that.

Mr. VERNEY: It depends a great deal on your client, you cannot lay down a hard and fast fee.

The PRESIDENT thought they should lay down a hard and fast fee. He would like each member to give his views individually.

Mr. HANCOCK the question of a great number of animals being tested with tuberculin was subject to a special arrangement. But when they were doing, say, anything up to 20, he had never met with the least objection to £1 1s. for the first, and 10/6 for the second and for each of the others up to 20. Over that number there should be a special fee. He also did a good deal of anti-abortion work. He had never met with the least objection to what he had charged, namely, 10/6 for a single one. If there were more it was always 5/- a time. He thought it was well worth it; they get a great deal back for their money. Anti-abortion was one of the finest things they had. I charge for the journey 1/- a mile.

Mr. COLEMAN said he charged for testing with tuberculin £1 1s. for the first; up to 15, 10/6; from 15 to 40, 7/6, and 40 and over, 5/- each, *plus* the journeys in each case. For anti-abortion he charged the journey and 2/6 each head. They had had no small quantities to do, they were all 70's, 80's, or 50's, so he could not tell what the charge would be in small cases. For intratracheal injection they charged 3/6 each when the numbers ranged from 50 to 80, *plus* the journey in all cases. With regard to mallein testing, they seldom got more than from 1 to 5, and charged £1 1s. each. He had got all the Inspectors in Wiltshire to sign a petition to the County Council, and as a result the fees for mileage had been increased from 1/- to 1/6, and from 5/- to 7/6 for inspections.

Mr. MALE: That usually has to do with the County Council, and you get a special scale.

Mr. VERNEY said he was concerned mostly with dairy farmers, and the charged the journey and 5/- each for tuberculin testing. For anti-abortion he charged the farmer 2/6 each; for intra-tracheal injections 1/6 each.

He had taken to refuse Insurance Companies unless they paid a proper fee.

Mr. WILLETT said he charged the same scale of fees as the Midlands.

The PRESIDENT: It is the only way to treat them. The fees should be referred to the National, who should call a meeting to see if some basis could not be found for the whole lot.

Mr. F. W. WILLETT said that he had added 25 per cent. to his bills with satisfactory results. Since the Midland scale of fees had come out he had increased his to correspond with them.

The PRESIDENT: To sum up, it seems that there is a variation. Five practitioners of the Royal Counties are each charging practically different fees. There is no uniformity. Therefore, we ought to bring it to a head, and soon. Each particular county seems to have a particular scale. Surely if we combined—and combination is everything—the Society should be able to have a definite scale of fees all round. Those who are better paid would not grudge the poorer paid members of their Society getting the same fees. I think there should be a committee of the Society who should lay down a set of charges and let the members of the Society subscribe to it as agreed—and stick to it. I would like the opinion of the members on that particular point. We are now in a stage of evolution. Everyone is combining, and we ought to combine a little more than we are doing.

Mr. HANCOCK: How can you make all combine with those who are not members of this particular Association?

The PRESIDENT thought that if a man was not a member of the Association, but received a copy of their rules, he would agree to keep his fees up. They wanted to start afresh, and take prompt action in the matter.

Mr. F. WILLETT said that when one saw the prices and turnover of practices advertised, they felt that something must be done to raise the fees. With regard to some of the practices advertised, if the owners had sons wishing to become veterinary surgeons it did not seem possible that they could become such on the incomes that the parents were earning.

Mr. HANCOCK: We are absolutely cutting our own throats.

Mr. F. WILLETT said that therefore they should set an example. It was fright which kept others from charging more. If the Association fixed a scale of fees, after a short time veterinary surgeons who were not members would fall into line.

The PRESIDENT said they might point out to a man outside the Association that he was undercharging, if he was doing so, and that, therefore, he was undercutting. He did not know that it would not be a matter for the Council of the R.C.V.S. if a man was undercutting another in order to get the work.

Mr. COLEMAN thought it was a great shame that there were so many different fees in the different counties. They should be more uniform.

The PRESIDENT said that that was what they were trying to draw into line. If the other men in their neighbourhood were out for the common good they would be much more likely to get members for the Association than at present. That was his feeling as President, and as he vacated the chair he would like to see it put on a strong basis. They should get a Committee formed by the Royal Counties to formulate a scheme, as other Societies were doing, lay down the price, and advertise it in their papers, pointing out that, as union is strength, it behoved all who are not members of the Society of their particular district to join now.

The HON. SEC.: Most veterinary surgeons around here are members.

Mr. HANCOCK said it would have much greater force if they would, in the meantime, draw up a short list of minimum prices which they, as members of that Association, had pledged themselves to charge.

Mr. VERNEY: I think it would be a good thing to have set fees.

The PRESIDENT said he was not interested, being in London, but he would like members of the Association to help forward a scheme like that.

Mr. F. WILLETT said that as labour was going to fix their fees, it was time the veterinary profession fixed their prices.

The PRESIDENT said that no doubt there would be a revival of everything; everything would go ahead after the stagnation of the war. If they were not prepared to go forward with the others they would be left behind.

Mr. HANCOCK moved that a small Committee be formed to formulate a list of fees for the special kind of work referred to, and report to the next quarterly meeting of the Association.

Mr. F. WILLETT seconded, and the following were appointed: Messrs. Male, F. Willett, Verney, Coleman, Hancock, and Parker.

The PRESIDENT said that if any man undercharged it should be considered an act derogatory to the Association, and he should be asked to resign. If the benefits of joining this Association were pointed out to practitioners he thought other members would join them.

#### "AFTER-WAR PROBLEMS."

The PRESIDENT: I would like to make a few remarks to form a basis for discussion. There is no doubt the repatriation and re-settling of the members of our profession bristles with difficulties. It is only right that the older men and the non-efficient should be returned first, more especially those who have practices of their own. The most useful and younger men would naturally be kept in the Army the longest. There must be a considerable number at the front who were not of much use, either through ill-health or want of adaptability, and had the war continued, it would have been the duty of the Veterinary Tribunal to have replaced these with younger men. But the question is would many of these be available as assistants. Therefore unless men applied for by their former principals are released, the difficulty of getting good assistants will be still of some duration. Then there is the question of men repatriated who had practices previous to the war. Some men went to a near neighbour saying they were joining up, and would the neighbours carry on for them, signifying their intention of coming back. Others did not go to their nearest neighbour, or opponent, but to a man seven or eight miles away, and asked him to do what he could for them while they were away. Naturally, the clients went to the nearest man in the town, namely, the opponent of the man who was serving. Is that man in that town expected to hand over all the clients that had come to him through the absence of the other man? Naturally, if he had been approached to carry on by the man who went away, it would be a matter of honour for him to hand over the clients when he came back—that was, providing they could get the clients to go back. They could not marry a client to a professional man. They might be more satisfied with the man they got in the interim than they were with the previous man. These are some of the difficulties I see. Some men had gone away without signifying their intention of coming back at all. They would expect—though they had no right to expect, to get all their clients back. They would feel raw if the man who had been serving them in the meantime did not hand them over. That would be a difficult matter for the College to solve. There is the case of a man who had been exempted by a Tribunal who was carrying on practice on behalf of the widow of a man who had "gone West" in the war. He has carried on the practice and paid 50 per cent. of the takings. The widow will have, under those circumstances, a difficulty in selling the practice. The man could not carry on for the widow indefinitely, and the

practice, when sold, would be practically the possession of the man who had been carrying on.

Mr. VERNEY thought it would be largely a question for the clients.

The PRESIDENT suggested that the Council of the R.C.V.S. should keep a register of gentlemen in the profession who were wanting eligible assistants. It would be a central plan, and a repatriated man passing through London could inspect the Register. A small charge should be made for the registration. They had to advertise now. If it was published in the papers that there was a Register of practices to be sold and the vacancies for assistants at the R.C.V.S., open to the perusal of any man returning from the front, it would go far to solve the question of the difficulty of assistants. After all, it is a matter between the employer and the employee whether they agree as to remuneration. But it seems a simple way to put men into communication with jobs when they come home.

Now, as to the Council of the R.C.V.S., I have had an opportunity lately of knowing there has been a lot of dissatisfaction with the Council itself. Someone suggested that the profession should "down tools," and demand the resignation of the whole Council. I turned round and said I prefer constitutional methods. When eight men retire from the Council every year, how many more put up? All admit new blood was wanted on the Council. Older men have done good work in their time and all honour to them, but they have outlived their utility on the Council, and in their places new and vigorous blood is needed. I would suggest that men who have gone out and done their bit, who have seen things, and had their minds broadened, are the men we want on the Council if we are to have vigorous treatment in the profession. It is their own fault if they do not get fresh men on the Council. Eight retire each year, and are usually nominated by their noble selves. If eight are required why do not twenty-four put up for the vacancies.

Mr. MALE: The eight need not be voted for.

The PRESIDENT: They should propose twenty-four men as candidates for the vacancies. Then within three years they would get a new lot of blood on the Council, and I must say, it is wanted. There are five or six men on the Council who were serving with the Expeditionary forces. To my mind those men, as soon as they accepted Commissions, should have resigned. They have been non-effective members of the Council for four years, and if those men put up again their patriotism would not be forgotten, and the profession would vote for them. Those men are nominally upon the Council, but had no voting power. What happened? Twice, or three times, through the absence of a quorum the Council were not able to carry out the recommendations of the Registration Committee.

Mr. COLEMAN: There has been a quorum only twice in three years.

The PRESIDENT: Certain branches of the profession—the Army and Board of Agriculture, should have representatives on the Council, but why each School should have one or two representatives I cannot conceive. Surely when any question affecting the Schools arose the Council could be depended upon to deal justly with it. It does not matter where the members of the Council come from—Ireland, Scotland, or any other part of Britain, providing they attend the meetings. But some only attend one or two meetings a year. What is the use of that? If we are going to have a vigorous, strong Council, we want a strong voting and debating power. Some of the present members of the Council are head and shoulders above the others, and these few lead the remainder—which does not tend to efficiency.

In conclusion, I understand that the Council hopes to bring in a new Bill early in the next Parliamentary

Session, and I wish every success to their efforts, and that's why I am averse to any revolutionary measure.

One leading man says so and so, and the whole of the others vote in that direction. He moved: "That the Royal Counties Veterinary Association agree that a resolution should be forwarded to the Royal College of Veterinary Surgeons urging upon them the advisability of keeping a Register of practices for sale, assistants wanting situations, and also vacancies for assistants, whereby those members returning to civil life from the Army may have the opportunity of being placed in suitable employment. And that a small charge be made to cover expenses."

Mr. COLEMAN seconded.

Mr. VERNEY quite agreed that there should be some new blood in the Council.

Mr. HANCOCK said he could not say he had been very much struck with what his friends had told him with reference to the doings of the Council. They seemed to be divided into two camps, so to speak. That was not recently, but formerly there appeared to be a House of Lords and a House of Commons, and what the House of Lords suggested the Commons adopted.

He liked what the President suggested as to the list of practices that required assistants and the practices that might be for disposal. It was a capital idea. They had to consider not only the chaps who had been practising, but a lot of graduates who were coming back and anxious to settle down. He took it that the essence of success with regard to a practitioner in the country was to put himself geographically in the right place. He suggested that the Council should put up a list that would be a guide to those young fellows not so start in the wrong place. Otherwise some of them would be committing suicide professionally. If some of them did what they proposed they would have such a fall that they would never recover from it. He heartily endorsed all the President had said with regard to the desirability of new blood on the Council. Every public body like that should be replenished with fresh blood as often as possible. If people would come forward with views that ought to be pushed forward they would receive the hearty support of the members generally.

Mr. MALE: If the position is as the President describes it, and the inefficient, through some cause or other, have to be liberated first—

The PRESIDENT: I am only suggesting that in the course of human nature the Army will let them go first. I have no authority to say so.

Mr. MALE thought that if that was the case it was very bad luck indeed. Many of the best men had single-handed practices which they had left at the beginning of the war and joined the Yeomanry and Territorials. If they were repatriated last it was very hard luck on them. It was a matter that the Council should go into with the Army Veterinary Corps, so that those men who had single-handed practices, and who had to leave them all in a hurry to go into the Yeomanry, should be repatriated first. In other walks of life single-handed business men were going to be liberated first, and so it ought to be in the veterinary profession.

If there was any doubt about the question it should be a matter for the Council to look into and act in the interests of men with single-handed practices. He had recently tried to get someone back, and he had a letter saying he did not see there was much chance. He did not know how they were going to judge as to who should come back and who should not. In any case they wanted to know definitely when they were coming back, whether this year or next, so that they would know what arrangements to make. Some definite statement should be made by the Army Veterinary Corps as to the system they were adopting with regard to the repatriation of these men. If there was no system they should formulate one.

With regard to anomalies in war time practice that, as the President said, would be a very difficult problem indeed. One could only look at it from a point of honour. The men who had been away should be given every facility to get back their clients. If the clients refused to go back it would be very awkward. He heartily agreed with the President on the resolution. It was an excellent idea. With regard to the men who had been in the ranks of the A.V.C. during the war, he was very much afraid they would have a large number of ex-A.V.C. sergeants dumped down all over the country. He had a letter in which the writer said, "am seeking suitable employment either as a *locum* or in some large stables. I am forty years of age and accustomed to horses, with a slight knowledge of other animals. I was a sergeant in the A.V.C. in France, and passed their vet's examinations . . ." Another sergeant in the A.V.C. wrote, asking if he knew of any job as assistant veterinary inspector under the Contagious Diseases of Animals Act.

The PRESIDENT said had had two similar applications.

Mr. MALE said that it was a great pity the men were put into the position they were, because very often they did as much as the veterinary officer himself: they prescribed, treated the cases, and almost the whole thing was left in their hands. If these men came back and competed with Army Veterinary Officers when in civil life they only had themselves to blame.

The PRESIDENT: I think you can trust the Council in their new Bill to scrap that.

Mr. COLEMAN said he would like to say a few words with regard to the Council. The position of the Council was caused entirely by the lethargy of the members of their own profession. The difficulty that any new blood had on that Council to bring forward fresh ideas was greater than words could express. They were shut up in a moment. What Mr. Willett said was perfectly true. Some men had done excellent work, but there were a few who ruled the roost entirely. He had fought very hard on two occasions to have the Committees elected individually, each name to be put up and voted upon. Once he succeeded by forming a little caucus around him. At this time he was on the Library and Registration Committees only. The following year he objected that the Library Committee meetings were over in about a moment and that nothing much was done. Last year he again raised the objection, and they placed him on four or five Committees. On two or three occasions he brought forward matters concerning the A.V.C., and at last they shut his mouth by putting him on the War Emergency Committee. He would certainly very much like to see a reconstruction of the Council. At the present time the majority of the Council followed the lead of and supported about four men, whatever they said. As to the representation of Schools, he endorsed what Mr. Willett said: it was necessary that the Schools should be represented on the Council, but not by so many members; it was tantamount to this—that the Schools ruled the profession. Anything that a School representative brought forward was almost sure to go down, and obtain support of the majority of the Council. The whole profession must cast aside its lethargy. The majority, as soon as they obtained their diploma, took very little further interest in the politics of their profession, but he believed they were waking up a little. He could not say too emphatically that the condition of the Council would not be altered until they had fresh blood in it and the profession generally takes more interest in their work. So far as he could see the Council did not interest themselves in the welfare of the profession itself beyond what he might call the legal administrative part. They did not seem to interest themselves in the things nearest the heart of the general practitioner. The Council

should interest themselves in everything in which the profession was interested and give them the lead.

The resolution was then put to the meeting and unanimously passed.

#### LINSEED POISONING IN CALVES.

Mr. MALE said that his attention was drawn to linseed poisoning in calves by the sudden death of five calves from about one to five months old. Three were found dead in the morning and two were still alive but very weak. The stomach was distended, there was diarrhoea, clay coloured faeces but no temperature. The membranes were of a bluish tinge. One of the calves died later. A post-mortem examination showed slight congestion of the fourth stomach and of the lungs; otherwise the organs were healthy. It seemed very strange, and he made inquiries as to the feeding of the calves. He found they had had some linseed cake. He had a look at the cake; it was from a very good make and in good order and they had only been fed with it recently or about 24 hours, when the illnesses commenced. It was stirred up with water and milk and given in a sort of emulsion. It was not boiled. He sent a sample to University College, Reading, who forwarded it to Dr. H. J. Lloyd for analysis. He reported that the fermentation test produced a very strong aroma of mustard and he was of opinion that this was the cause of the troubles. He also said "It is not improbable that the enzyme in the mustard might evolve hydrocyanic acid from the linseed. But I have not tested this, and know of no evidence." It seemed to him (Mr. Male) very strange that that mustard should cause the symptoms he said; and he was not satisfied. It looked more like prussic acid poisoning especially considering the quickness with which the calves died.

Mr. VERNEY: Was there any fulness and rigidity?

Mr. MALE: Yes. He thought it over a lot, and consulted the authorities about mustard poisoning, but could not get any help. Then he happened to see an article from the Board of Agriculture which seemed to solve the whole problem. The article was as follows:—

"From time to time the attention of the Board is directed to cases of illness, or even death, of calves resulting from the use of linseed or linseed cake. In view of the widespread popularity of these foods for calf-rearing, it is obvious that such cases of trouble must be comparatively rare, but they serve to direct attention to the fact that a certain amount of care is necessary in the feeding of linseed or linseed cake to young stock. The risk is negligible with adult animals, and in the case of young animals only arises when the linseed meal or linseed cake has been *treated with water some little time before feeding*. It is due to the fact that linseed contains two substances which in presence of water tend to interact and produce small quantities of the deadly poison, prussic acid. This does not prevent linseed and linseed cake being very good and safe foods when properly used. All that is necessary is that if the linseed is treated with water at all it must be kept for a little time at practically *boiling temperature*. The safest plan is actually to boil the linseed with the water. If this cannot be done conveniently, and "scalding" is resorted to, it is necessary that the water should be absolutely *boiling* as it is poured on the meal, using at least *ten times* as much water as meal (1 gallon water to 1 lb. meal) and stirring carefully until quite free from lumps. If this procedure is followed closely the mixture should be quite safe to feed, especially if prepared *not long* before feeding time.

As a rule home-grown linseed offers less risk of poisoning than linseed imported from hotter climates, but there is no linseed meal (or cake) which cannot be rendered quite harmless if properly prepared for feeding in the manner indicated."

He brought the matter forward because he had never come across a case of poisoning in calves in that way. But evidently it had occurred before. As it was very fatal he thought it would interest the members. He would like to hear if any of them had found any similar cases.

Mr. VERNEY: I always advise that the linseed should be well boiled before giving it to young stock, but have had no cases of poisoning.

Mr. COLEMAN: I should like to thank Mr. Male for bringing the matter forward. I have never thought of anything of the sort before.

#### CALF DIPHTHERIA.

Mr. MALE: During the last two or three years I came across a number of outbreaks of calf diphtheria, and as there was not much literature on it and the cases were rather interesting, I thought a description of them might be useful. Other names for the disease are contagious and ulcerative stomatitis.

The disease is due to the necrosis bacillus, and it affects the young calf soon after weaning up to two or three months of age. Sometimes the outbreak is very virulent and a lot of calves die. At other times it seems to run more of a chronic course, and the calves recover. In one farm no less than 50 calves had died in the course of a year before I was called in. They could not wean any calves, and were in great trouble about it. I have usually found it where calves were kept in too great numbers in one shed, where the hygienic conditions were bad, where there was not enough sunlight, especially, too, when the food is poor. I have found one of the best means of treatment is to feed them well and give them plenty of milk. In the acute cases the calves are very ill. They lay down, are weak, have swollen glands, and all round the throat is very much enlarged. There are ulcers on the nose, on the lips, tongue and inside the mouth. When the mouth is opened they would see a white necrotic material on the side of the mouth and at the back of the throat. He supposed that was why it was called diphtheria. The calves dribble at the mouth, have a high temperature and are affected with diarrhoea. They will not eat, and breathe with difficulty with mouths open. They die very rapidly. I have seen as many as six and eight in one place dead with it. In other cases the disease seemed to be less acute; the calves look bad, do not thrive, and have necrotic ulcers in the nose, etc. A post-mortem examination shows great congestion of all the organs, especially the lungs and liver. All the glands are inflamed and congested, especially round the throat. There is also a good deal of inflammation of the bowels. As to treatment I find that putting them under the best hygienic conditions, getting them in the sun, separating them in several lots, the worst cases in one lot, those that are recovering in another lot, and the healthy calves in another lot; and then feeding them with plenty of milk. [Mr. VERNEY: That is what they don't get.]

I find that in the way of treatment it was extraordinary how they picked up with Permanganate of potash and Potassium chlorate. In the way of preventive treatment I advise the isolation of the affected calves. I do not allow a man to suckle the calves, because if they licked his fingers and he went from one to the other the disease would be spread in that way. I make them drink out of a bucket or a bowl, and disinfect it after each calf has drunk; or have a separate bucket for each calf. I also isolate the attendant, and do not allow him to milk, or, if he does, to do that before he attends to the calves, otherwise the organism would get into the milk and infect the healthy ones. I advise cleaning them out very frequently and sprinkling slaked lime over the bed of straw. When these measures are carried

out there seems to be no difficulty, and they soon get rid of the disease.

Mr. COLEMAN wished to again thank Mr. Male for his remarks, which were exceedingly interesting. He did not remember having come across such cases.

Mr. VERNEY said he had not had similar cases.

Mr. PARKER: I have never had any.

Mr. MALE: My experience seems to be unique,

The PRESIDENT thanked the members for the support they had given him during the three years that he had occupied the chair, and he was to be congratulated that at the last meeting, though it was small in numbers, it was most prolific in discussion. He thought they had moved in the right direction in getting a few remarks on the Council, and the work they had to look forward to with regard to repatriated men. They had also had two very interesting cases from Mr. Male, which showed them what difficulties the profession often had to face.

The HON. SEC. proposed a very hearty vote of thanks to the President for his splendid services during the past three years. No one knew the difficulties he had had to contend with during the war but he had stuck to his post and attended every possible meeting; and had helped the Association in more ways than one. He had induced a lot of new members to join, had brought his friends down, and had been simply splendid. (Applause.)

He was very pleased to propose that they give him their best thanks for all he had done.

Mr. COLEMAN: I shall be very pleased to second that.

Mr. VERNEY: I support it in every way. He has kept the society going under very adverse circumstances.

The vote was very cordially passed.

The PRESIDENT said his heart was in the work, and he had only been too pleased to do all he could.

## ARMY VETERINARY SERVICE

War Office, Dec. 20.

The following dispatch has been received by the Secretary of State for War:—

General Headquarters, Nov. 8, 1918.

My Lord,—I have the honour to submit a list of names of those officers, serving, or who have served, under my command during the period February 25, 1918, to midnight, September 16-17, 1918, whose distinguished and gallant services and devotion to duty I consider deserving of special mention.

I have the honour to be, my Lord, your Lordship's obedient servant,

D. HAIG,  
Field-Marshal, Commanding-in-Chief,  
The British Armies in France.

### COMMANDS AND STAFF.

Capt. (actg. Maj.) W. Ascott, R.A.V.C. (T.F.); Capt. (temp. Maj.) J. S. Bowden, R.A.V.C. (T.F.); Lt.-Col. (actg. Col.) R. L. Cranford, F.R.C.V.S., R.A.V.C.; Maj. P. W. Dayer-Smith, R.A.V.C. (T.F.); Capt. (temp. Maj.) R. A. Goode-ridge, R.A.V.C.; Capt. (actg. Maj.) E. Hearne, R.A.V.C.; Capt. (actg. Maj.) S. E. Holmes, R.A.V.C. (S.R.); Capt. (temp. Maj.) T. Lishman, R.A.V.C.; Maj. L. MacDonald, R.A.V.C.; Maj. (actg. Lt.-Col.) J. A. B. MacGowan, R.A.V.C.; Maj. (temp. Lt.-Col.) A. W. Mason, R.A.V.C. (T.F.); Col. and hon. Maj.-Gen. J. Moore, C.B., F.R.C.V.S. (late R.A.V.C.); Maj. W. W. R. Neale, R.A.V.C.; Capt. (temp. Maj.) C. E. Neill, R.A.V.C. (T.F.); Maj. (temp. Lt.-Col.) W. A. Pallin, D.S.O., F.R.C.V.S., R.A.V.C.; Capt. (actg. Lt.-Col.) E. W. Parks, R.A.V.C. (T.F.); Capt. (actg. Maj.) J. F. Rankin, R.A.V.C. (T.F.); Temp. Capt. (actg. Maj.) C. W. B. Sikes, R.A.V.C.; Capt. (actg. Maj.) F. B. Sneyd, R.A.V.C. (S.R.); Capt. (temp. Maj.) W. H. Taylor, R.A.V.C.

The King has been pleased to give orders for the following promotions and appointments for valuable services rendered in connexion with the war in India (dated June 3, 1918).

O.B.E.

Lt.-Col. GEORGE KEMP WALKER, C.I.E., F.R.C.V.S., Ind. Civil Vety. Dept.

War Office, Dec. 19.

The names of the following have been brought to the notice of the Secretary of War for valuable service rendered within the Union of South Africa in connexion with the Campaign in German South-West Africa and German East Africa:—

Maj. (temp. Lt.-Col.) J. G. Bush, S.A.V.C.; Maj. A. Goodall, S.A.V.C.; Capt. (temp. Maj.) S. I. Johnston, S.A.V.C.

Buckingham Palace, Dec. 19.

The King held an Investiture in the Ball Room of the Palace at 10.30 o'clock this morning.

The following Officers were severally introduced into the presence of The King, when His Majesty invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted:—

THE MOST DISTINGUISHED ORDER OF  
ST. MICHAEL AND ST. GEORGE.

Lieut.-Colonel FRANK BALDREY, R.A.V.C.

THE DISTINGUISHED SERVICE ORDER.

Major PERCY SIMPSON, R.A.V.C.

Buckingham Palace, Dec. 21.

His Majesty held an Investiture in the Ball Room of the Palace at 10.30 o'clock.

The following were severally introduced into the presence of His Majesty, when The King invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted:—

THE MOST DISTINGUISHED ORDER OF ST. MICHAEL AND ST. GEORGE AND THE DISTINGUISHED SERVICE ORDER.

COMPANION—Col WILLIAM SMITH, R.A.V.C.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Dec. 19.

REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Capt. to be actg. Maj.:—T. L. Shea (Oct. 8, 1917).

Dec. 21.

Temp. Qrmrs. and Lieuts, R.A.V.C., to be Capts. under Art. 330, R. Wt. for pay and promotion:—J. Daunt (Nov. 2); H. Barrs (Nov. 9).

## DEMobilIZATION.—NO PRESENT RELEASE.

The War Office desires it to be known that officers and men cannot at present be demobilized from the following corps, which are essential to the work of demobilizing the Army:—Royal Army Service Corps, Royal Army Ordnance Corps, Royal Army Veterinary Corps, Remount Corps, Directorate of Military Railways (France), and Army Pay Corps.

Applications from members of these corps cannot be considered at present, even on the production of approved offers of employment from pre-war employers, but the fact that employment awaits an individual is to be recorded with a view to his being demobilized at as early a date as possible.

## SWINE FEVER ADMINISTRATION.

*The Editor, "The Veterinary Record."*

Sir,

I am very pleased to see letter in to-day's *Record* on this matter, as I have also considered as to whether one ought not to ventilate one's views on the point! It is most humiliating and unfair for an old established practitioner in a well known practice to be called in by his clients and to be forced to tell them that he cannot proceed further, and then to hear later that a young practitioner some miles away has attended; and in at least one case known to the writer the M.R.C.V.S. acting for the B. of A. is well under military age!

It is scarcely the way to make one very loyal to the Veterinary department of the B. of A.; and in addition, as your correspondent states, the distance involved is often great—so much for economy in petrol as practised by a government department.

21/12/18

Yours etc., FED UP.

Dear Sir,

I have read "Fairplay's" letter with great interest and consider he has faithfully represented the views of the country practitioner on the swine fever business. So far I have failed to see why veterinaries should be sent long distances to take over work which could be just as well—and in some instances more expeditiously—carried out by the man on the spot.

I prefer to remain "incognito" so will subscribe myself your "NEW CORRESPONDENT."

Sir,

I have read "Playfair's" letter re administration of Veterinary Department of Board of Agriculture, and consider it savours very strongly of jealousy. His *modus operandi* of supplying all Veterinary Surgeons with forms is impracticable; one might just as well say that every doctor should be a M.O.H.

If the duties of the Board's Veterinary Officer are so onerous, and limited to killing pigs and forwarding viscera to London, as Playfair states, then I should suggest the appointment of all butchers as fully qualified for the position.

I should have thought that with "Playfair's" extensive practice among prize stock he would not have wanted to stoop to the killing of pigs and forwarding of viscera to the Board of Agriculture.

Yours etc., COUNTRY PRACTITIONER.

## Linseed Poisoning.

The following letter appeared in a recent issue of *The North British Agriculturist* and *The Scottish Farmer*. The official leaflet states distinctly that cases of this poisoning occur sporadically, and this experience endorses the statement. It also demonstrates that the causal trouble is still unknown—whether of soil, of ripeness, or of storage:—

"I have, for upwards of twenty years, invariably fed my calves on some form of linseed—linseed oil cake meal, etc., and though preparing these meals in the very way to encourage poisoning (according to the article referred to), I never saw any bad results. In fact I have had each year about the best calves to be seen in the district. I would like to hear what others have to say on the subject. I first mix the meal in sufficient cold water to form a smooth paste, then allow it to stand for twelve hours. An equal amount of hot water

is added before feeding, the whole being mixed with skim milk.

Mixing oilcake meal with boiling water is impossible as it forms into lumps which cannot be broken up. Mixing with cold water and then bringing to the boil works well, but I am afraid most farmers would consider this too much trouble."

## OBITUARY.

GUILLAUME FRANÇOIS MARAIS, B.A., B.Sc., M.R.C.V.S.

Volksrust, Transvaal.

Graduated, Lond: Dec. 1913.

## Death of Mr. G. F. Marais.

Volksrust, Saturday.—The death of Mr. Guillaume François Marais, Government Veterinary Surgeon at Volksrust, has deeply moved the community. When the epidemic assumed alarming proportions, the committee in charge of relief measures sent to the Government an urgent appeal to release for the time being Mr. Marais from Government duties that he might assist in fighting the plague. This being granted, the deceased officer threw himself with energy into the work, toiling day and night. His duties took him to the Railway Compound, where he ministered to the stricken families, and in this notorious region contracted the disease which cost him his life. A well-known Pretoria doctor, a friend of deceased in his student days who, on learning of the illness of his friend at Volksrust, came down specially to help him, has written a memoir eulogy, in which he condemns the compound. After Mr. Marais' death, will the Railway Administration, it is asked, now rise to its responsibilities and provide decent sanitary dwellings for its white workers—Deceased, who was 33 years of age, was transferred to Volksrust from Pretoria. He had endeared himself to the community, and was unusually esteemed. At the the coffin was covered with floral wreaths.—*Rand Daily Mail*.

[The date of death is not given. The correspondent who sends us the cutting dates from the Veterinary Research Laboratory, Onderstepoort, Nov. 14, and we may conclude from that that Mr. Marais' death occurred about a week previously.]

ROBERT ELLIOTT, late Major R.A.V.C. Putney,

London, S.W.

N. Edin.: Dec., 1902.

Major Elliott, who had been in ill-health for some time past, died on Friday, 20th inst.

Mr. LAWRENCE C. TIPPER, of Messrs. B. C. Tipper & Son, Birmingham, received a pressing invitation to come forward as a non-party candidate for the Mosley Division of Birmingham. After considering all the circumstances, he decided not to seek election. Mr. Tipper has worked for years to secure allotments and small holdings, but he considers it illusory and foolish to suggest their creation on the gigantic scale foreshadowed. He believes in placing suitable men on the land in suitable places. Along with this it must be provided that the agriculturists get a satisfactory recompense for their labour as the artisan.

Original articles and reports should be written on one side of the paper only and authenticated by the names and addresses of writers, not necessarily for publication.

Communications for the Editors to be addressed

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1591.

JANUARY 4, 1919.

VOL. XXXI.

## AN ACCOMPANIMENT TO DEMOBILISATION.

At the meeting of the Royal Counties V.A., reported last week, the probability that we may have "a large number of ex-A.V.C. sergeants dumped down all over the country" in quest of veterinary employment was referred to by Mr. Male, and several instances in point were mentioned. There is no doubt that this is a very real and serious danger; and we should be prepared to face it without any illusions.

The ex-N.C.O. who has gained some Army veterinary experience has long been familiar to us. Long before the Army Veterinary Service possessed a subordinate staff of its own, ex-farrier sergeants and the like were accustomed to advertise themselves as being capable of taking "complete veterinary charge" of studs. Some of them were by no means ignorant, and succeeded in obtaining much work that ought to have been performed by our profession. The present N.C.Os. of the R.A.V.C. are much more dangerous than these men, because generally more efficient. They have been trained by and have worked under veterinary officers, and many of them have now had considerable experience in equine diseases and injuries of almost every description. Many, also, in these days of universal service, are much better educated than were most N.C.Os. of the old voluntary Army. The best of them are probably far superior to the bulk of the now rapidly disappearing Registered Practitioners; and they may prove the most formidable unqualified opponents we have ever had to face.

A good deal of this opposition seems practically inevitable. The Council can deal with men who infringe our Act; but it is not in the least likely that any additional legislation against unqualified practice can be obtained. Thus it will be possible for these men to compete a good deal with us on an unqualified footing; and we must see to it that their hands are not made stronger than they already are.

One immediate precaution may do something to lessen the evil. Veterinary officers can exercise the greatest care in the wording of any testimonials or recommendations to men who have served under them in the R.A.V.C. This does not mean that deserving subordinates should not be well recommended; it simply means that all such recommendations should be framed to exclude the idea of anything like complete veterinary knowledge and efficiency on the part of their possessors. With care, this can be done without injustice. A little carelessness, on the other hand, may produce a testimonial which may be used as a glowing advertisement.

## OUR REPRESENTATIVE CONSTITUTION.

In an article entitled "Medical Schisms," the Medical Correspondent of *The Times* discusses (Dec. 30) the present situation of domestic politics in the medical profession. The recently-formed Medico-Political Union has been steadily gaining ground on its rival, the much older organisation "The British Medical Association." The latter is making strenuous efforts to become the representative professional body, though its future prospects are somewhat dubious.

"There is no body, indeed, which can claim to speak for all the doctors in the country except the General Medical Council, and the claim of that body has scarcely been advanced seriously. The extent of this misfortune is far greater than generally recognised, and will increase as time passes. It is in the nature of things that statesmen should wish to have medical advice on matters of medical policy. Whom are they to consult?"

The Royal College of Physicians, nor the Royal College of Surgeons, nor the British Medical Association can be called representative, and the suggestion is made that the time has come to remedy this defect by setting up a central medical representative body.

"Every registered medical practitioner should have as many votes as there may be places on this body and voting should be by post. Elections should take place once a year. The new body should thus be representative of the profession as a whole, and could deal in the name of the profession with any minister."

And the public would have the advantage of considered medical advice on the great health questions about to be dealt with.

The organisation here proposed as an ideal for the medical profession follows exactly the lines of the constitution of the Council of the Royal College of Veterinary Surgeons. While the Royal College of Surgeons still deprives its members who are not Fellows of the right to vote, the veterinary profession vigorously repudiated this anomaly in those lively days preceding the 1892 Charter, and it was then and there abolished. Something has been said recently on the question of the constitution of the Council, and the need for "new blood" but it is obviously not the system which is at fault. If the Council is not what it should be the remedy lies easy to hand. The Council is elected by the suffrages of the profession, and if it is alleged that it is not representative of the profession, the blame is on the profession and not on the Council. If the profession can find candidates for election to the Council, who will do better than any of the present members, now is the time to nominate them. The voting papers for the next election will be sent out to members outside the United Kingdom at the end of January.

There is one reservation as to the selection of councilmen which should not be lost sight of, especially in so small a body. A member is elected for a term of four years, and in most cases this term is considerably increased by re-election. In an emergency, such as, for instance, the Charter of 1892, it may become advisable to elect men who have strong opinions on a particular question: but unless the men so elected are men of known capacity, this procedure may result in burdening the Council with a group of nonentities for years afterwards.

### TRIORCHIDY IN THE HORSE.

In the spring of 1918 you published several communications anent a case of castration which ended in an unfortunate manner to the operator and also to the profession. According to the published evidence on both sides I came to the conclusion that the practitioner, against whom the case went, was speaking the truth—that he did remove two testicles. I intended at the time to offer some remarks on the case, but, unfortunately, something occurred to attract my attention elsewhere and so forgot the incident.

Personally, I think the case was one of *triorchidy*—one in which the animal was the carrier of three testicles, of which only two were apparent at the

Sometimes the third testicle may be apparent at the time of the removal of the other two, but mostly this descends at a later date, even as late as a year after the first operation.

There are many such cases recorded in our annals, and it has also been described by several masters of veterinary surgery.

It is a pity the victim in the law case did not proceed for a new trial and call expert evidence to clear not only his own good reputation, but also to safeguard the profession against a further charge of unskilfulness—which it amounted to.

SCRUTATOR.

### THE CENTRAL VETERINARY SOCIETY.

[NATIONAL V.M.A.—SOUTHERN BRANCH.]

An ordinary general meeting was held on Thursday, December 5th, at 10 Red Lion Square, London W.C., the President, Prof. G. H. WOOLDRIDGE, occupied the chair.

The following signed the attendance book:—Messrs. N. Almond, J. B. Buxton, W. R. Davis, H. Gray; Maj. F. Hobday, R.A.V.C.; Messrs. Herbert King, W. S. King, J. W. McIntosh, H. G. Parkin, W. Perryman, R. A. Philp, J. Rowe, F. G. Samson, C. Sheather, F. H. Stainton, W. N. Thompson, and Hugh H. MacCormack, Hon. Sec.

*Minutes.* On the motion of Mr. Davis, supported by Mr. Almond, the minutes of the previous meeting were taken as read.

*Correspondence.* The SECRETARY announced that he had received postcards from Mr. Woolston and Mr. J. Willett regretting their inability to attend, and also a letter from Mr. Stroud, intimating that he was a victim of influenza.

It would be remembered that, at the last meeting of the Society, he (Mr. MacCormack) had been requested

to communicate with Mr. Whitlamsmith with regard to that gentleman's resignation. He had made this communication, and had received the following reply:—

"Thanks very much for your letter and many thanks to the Fellows. I have been going to resign for years, as I never seem able to get to the meetings. I shall be pleased if you will now accept my resignation. Kindest regards."

The PRESIDENT: As Mr. Whitlamsmith adheres to his resolution to resign, we have no alternative but to suggest that the resignation be accepted. Mr. Rowe proposed, and Mr. Samson seconded a motion to that effect, which was accordingly carried.

The Secretary further announced that he had received *Bulletin No. 77* from the Agricultural Research Institute, on the subject of Camel Feeding Experiments, by Mr. H. E. Cross.

The PRESIDENT said that the articles by Mr. Cross on the subject named were good articles, and he thought the thanks of the Society were due to Mr. Cross for the *Bulletin* he had sent. A letter of thanks from the Society would be sent to Mr. Cross.

### RE-ELECTION OF PROF. J. MACQUEEN.

Prof. WOOLDRIDGE recalled the fact that about a year ago Prof. Macqueen had expressed the opinion that in existing circumstances the Society would do well to adjourn its meetings, and, consistently therewith, had withdrawn from the Society, in spite of the request that he should retain his membership. Prof. Macqueen had, however, intimated that when hostilities ceased he would doubtless rejoin the Society. Also he had told the speaker, before the signing of the armistice, that he intended to proceed to re-election, as he felt the war was drawing to its end. Meantime, the Professor had sent in his request to the Secretary, and the matter had been put on the agenda. [The President therefore called for a ballot, which, being taken, showed that Prof. Macqueen had been unanimously re-elected.]

### COCCIDIOSIS IN THE RABBIT.

J. B. BUXTON, F.R.C.V.S., D.V.H.

The increasing value of the rabbit as an article of food during the last few years has proportionately increased the significance of epizootics to which these animals are susceptible. The prevalence of coccidiosis is undoubtedly far more extensive than is generally supposed, and is of considerable economic importance.

The predisposing causes of the disease are primarily, of course, the introduction into the rabbitry of infected stock, insanitary conditions of housing, and general unhygienic principles of feeding, etc.

The causal agent is the *Coccidium oviforme* (C. cuniculi or Eimeria stiedæ).

The Coccidiidae are sporozoa of the sub-division Telosporidia, in the life-cycle of which the re-productive phase is distinct from the trophic.

The Coccidia are small oval bodies with granular protoplasm and a nucleus.

Reproduction is both sexual (Sporogony), and asexual (Shizogony). The form of parasite most commonly observed consists of an oval cell 20-40  $\mu$  by 15-20  $\mu$  with a well-marked wall or cell envelope surrounding a mass of granular protoplasm which frequently only partially fills the cell, and has a more or less centrally placed nucleus. Such forms represent the final stage of the life history of the parasite in the animal body; they are called Oocysts.

The life cycle of the parasite is somewhat complicated, but in order that the spread of the disease may be satisfactorily limited some knowledge of the manner of reproduction and of its various phases is essential to the clinician. The oocysts are expelled from the body with

# COCCIDIOSIS IN THE RABBIT.

To illustrate paper by Mr. J. B. Buxton, F.R.C.V.S.

the faeces, and under favourable conditions of warmth and moisture the cell contents divide into two, and then into four spherical bodies called Sporoblasts. These sporoblasts elongate and become sporocysts, each of which later divides into two crescentic bodies—falciform corpuscles or sporozoites.

The mother cyst, that is the cyst containing the original sporocysts is very resistant to adverse conditions and retains its vitality for very considerable periods, probably longer in dry than in moist surroundings.

If a rabbit ingests such a cyst, the wall becomes dissolved and the sporocysts are liberated. These in turn, rupture and set free the sporozoites or falciform corpuscles. These are actively motile bodies which penetrate, by means of their sharp anterior extremities, into the interior of the epithelial cells of the small intestine or bile ducts, lose their motility and become schizonts.

**Schizogony (Asexual reproduction).** The schizont is a spherical, non-encapsulated body which contains a nucleus and several vacuoles; and it grows at the expense of the epithelial cell. The nucleus soon divides into a number of daughter nuclei each of which becomes surrounded by a mass of the cell protoplasm which assumes a crescentic form, so that the bodies resemble the quarters of an orange, these are called merozoites. The epithelial cell ruptures and the merozoites are set free, many die, but others penetrate fresh epithelial cells where they (a) lose their motility, and again become schizonts, so repeating the process, which is extremely rapid, and accounts for the very quick spread of the disease in the infected animals, or (b) become converted into male or female elements—microgametes or macrogametes.

**Sporogony (Sexual reproduction).** Cells which are destined to become macrogametes increase slowly in size and develop numerous chromatin granules. The macrogamete by means of contractile movements reaches the surface of the epithelial cell where it becomes spherical, non motile, and exhibits a well marked nucleus and an enveloping membrane with a break in its continuity at one point, the micropyle.

Cells which are about to become microgametes grow rapidly, the nucleus breaks up into numerous fragments, which become arranged round the periphery of the microgametoblast, and each nucleus then becomes surrounded by a mass of protoplasm. The nuclei become elongated and comma shaped, and two flagella appear towards the anterior extremity. These are the microgametes which on account of their flagella are motile, and soon become free of the microgametoblast and closely resemble the spermatozoa of the higher animals.

The microgametes are attracted by the macrogametes, a single male element penetrates the female cell at the micropyle which then closes. The microgamete fuses with the nucleus of the macrogamete so forming the oocyst or zygote and the cycle is completed.

#### LESIONS.

There are two types of lesions—the hepatic and the intestinal. The former may be called the chronic form of the disease when it occurs alone, and the intestinal or the coexistence of the two types constitute the acute form of the disease.

The hepatic type is the more frequently observed, because it is the less fatal and the more obvious on post-mortem examination. It is characterised by the formation of abscesses which originate in the epithelium of the bile ducts and have a ramified appearance. These abscesses may be few in number and appear as small whitish areas in the liver substance, or they may be so numerous as to give the organ a distorted, lumpy,

appearance. The disease may resolve spontaneously, in which case, upon post-mortem examination, one only sees cicatricial scars upon the surface or in the substance of the liver.

In young rabbits the disease frequently runs a very rapid course, in which case the hepatic lesions are more generalised, the bile ducts are dilated and white streaks resembling the roots of a tree, produced by these dilated ducts, are seen radiating in all directions.

The process begins by the invasion of the epithelium of the bile ducts by the coccidia which result in the destruction of the cells. Later there is a marked hyperplasia of the epithelia and a papillary proliferation of the bile ducts so that they become much branched cavities instead of simple canals. The connective tissue becomes hypertrophied, producing at first a venous congestion and later atrophy of the gland.

The internal organs are pale in colour, while the blood appears to be watery and there is an absence of fat in the abdominal cavity.

A section of the liver, upon microscopic examination shows that the abscesses are formed by greatly distended bile ducts, partly fused together and separated from the hepatic tissue by fibrous tissue, these contain immense numbers of coccidia in the epithelial cells lining the ducts.

In the intestinal form, which is most frequently brought under one's observation in the case of young rabbits, the lesions are most marked in the first few inches of the small intestine. There is a general redness and some thickening of the mucous membrane, with small areas of a more intense colour which later develop into minute nodules. Occasionally the area of congestion involves the stomach also, in which case the organ contains a small quantity of watery mucus, but no food.

Microscopically a scraping of the mucous membrane reveals numbers of the coccidia. A section of such an intestine shows large numbers of the parasites in the epithelium of the tubular glands.

#### SYMPTOMS.

When one's attention is called to an outbreak of the disease in a colony, the adult animals, although suffering from the chronic hepatic form of the disease may show no symptoms. Young rabbits however appear to be generally unthrifty, their coats are staring, the mucous membranes are pale and they are badly nourished and obviously "pot bellied." Diarrhoea is often present, but the faeces are seldom blood stained. There is loss of appetite, the emaciation gradually progresses, the animal becomes slowly weaker and finally dies.

In other cases the animal is "pot bellied" and generally unthrifty, but, the appetite remains fairly good, and death takes place suddenly as a result of an obvious intoxication.

#### DIAGNOSIS.

During life the condition may be diagnosed by the microscopic examination of watery suspensions of the faeces. The oocysts appear as oval bodies closely resembling the ova of nematode worms. In some instances parasites are seen in which the protoplasmic contents show changes associated with the earlier stages of reproduction. In chronic cases it is usually necessary to make many examinations of the faeces at frequent intervals, since the expulsion of the oocysts is not continuous, but depends upon the periodic breakdown of old lesions.

#### TREATMENT.

**Preventive measures.** When the disease makes its appearance in the rabbitry the animals which show no symptoms should be removed to clean and hygienic quarters and should be strictly isolated. All obviously

infected animals should be killed off, but when this is not possible they should be segregated into small groups.

The tame rabbit is by nature a cleanly animal, and invariably selects a certain area of its habitation for the deposit of excreta. Cleanliness is essential, all faeces should be burnt and the hutches scrubbed thoroughly with a hot solution of Lysol or other reliable disinfectant. Foodstuffs which may by any chance have become contaminated should be used only for animals which are known to be infected. Since the parasite is transmitted from animal to animal by means of the faeces or food contaminated by them, any ground upon which infected animals have been should be dressed with lime and, when possible, dug over.

**Curative treatment.** It is better not to attempt curative measures. If, however, it is decided to do so, tonics should be given, especially sulphate of iron and, because the animals eat it so readily in their food, gentian. In the intestinal form and in the early stages of the disease, disinfectants, such as Chloramine T, may be given by the mouth in small gelatine capsules. The food should consist of dry concentrated material and wet greenstuff. Roots and bran should be avoided. Clean cold water should be available at all times.

#### MEAT INSPECTION.

From this point of view the flesh of infected rabbits cannot be considered as dangerous to health. In the acute type of the disease its value is, of course, impaired owing to the serious disturbance of health, and in severe cases in which there is marked emaciation the flesh would be considered unfit for human consumption.

#### COCCIDIOSIS IN OTHER ANIMALS.

*C. oviforme* is considered by Guillebeau as the causal agent in red dysentery of cattle (dysentery haemorrhagica coccidiosa) frequently seen in parts of Switzerland, and occasionally in other European countries. The parasite may be demonstrated in the blood-stained faeces and in the mucous membrane of the colon of infected animals. It is from 20 to 25  $\mu$  by 15  $\mu$ . Infection experiments have reproduced the disease.

A coccidiosis of sheep has been observed in the United States of America and in Europe. The lesions are usually confined to the intestinal mucosa and especially that of the small bowel, but may also be seen occasionally in the fourth stomach. The mucous surface becomes studded with small nodules from  $\frac{1}{4}$  to  $\frac{1}{2}$  of an inch in height. The coccidia are found in the epithelium of the tubular glands associated with the conical outgrowths.

In birds, *C. avium* or *Tenelleum*, which is probably identical with *C. oviforme*, is responsible for several pathological conditions. Blackhead or enterohepatitis of turkeys, some forms of white diarrhoea of chicks and of young artificially-reared pheasants, and possibly some forms of roup in fowls have been shown to be caused by coccidia.

The coccidium described as *C. perforans* or *C. hominis* and found in the epithelial cells of the intestine of man and of rabbits has been shown by Rivolta and Metzner to be the same species as *C. cuniculi*.

Cubler and Silcocks have described the occurrence of purulent cysts in the human liver in which coccidia, identical with those of the rabbit, were found to be actively multiplying.

*C. bigeminum* is responsible for a haemorrhagic enteritis of dogs and cats, and is probably the same parasite as that found by Kjellburg in the intestinal villi of a man and should be classified with the diplospora—a genus closely related to the coccidia, and characterised by the fact that the oocyst produces two sporocysts each of which gives rise to four sporozoites.

*C. fuscum* was considered by Olt to be responsible for a granular eruption on the pig's skin. As a result of the examination of serial sections of such skin he found that the pathological process arose in the sweat glands, in the epithelia of which coccidia of a somewhat brownish colour were multiplying.

The genus coccidium comprises about forty species which are parasitic in mammals, birds, reptiles, fish and insects.

#### DISCUSSION.

Mr. GRAY opened the discussion. Personally, he thanked Mr. Buxton for his interesting paper, because he felt that the subject, which came within the province of veterinary medicine, was one which should be ventilated by the veterinary profession, instead of being left to outsiders to bring before the public. Having been a rabbit keeper all his life, he knew something of the disease under discussion. He noted, however, that Mr. Buxton appeared to overlook the fact that in this country, coccidiosis had been observed, in cattle and sheep, by several members of the profession, from Sir John McFadyen downwards. Probably it was much more prevalent than the majority suspected. Mr. Buxton had stated that the parasite which caused the disease in rabbits was the same as that which occasioned it in birds. Anent this he would say that Dr. Fantham, the distinguished zoologist of the School of Tropical Medicine, Liverpool, had investigated the disease in birds more considerably than anyone else in the country, and had concluded that the coccidium of the rabbit and that of the bird were different. This view agrees with that held by most of the eminent zoologists who have given it attention on the Continent of Europe.

Mr. Buxton had remarked, further, that the disease was common in wild rabbits, a remark supported by Dr. Sheridan Delépine, of Manchester, who, many years ago, asserted that the disease occurred in 92 per cent. of wild rabbits. Certainly in some years it was common. The speaker recalled his own experience in endeavouring to "pot" rabbits in the outskirts of woods during summer evenings, and had found that the animals he succeeded in "potting" were generally affected by coccidiosis. He assumed that those that were alert in not allowing him to get within range of them were the more healthy rabbits.

With regard to tame rabbits, he was of opinion that infestation in country districts was mostly caused by owners collecting food from plantations and other places where wild rabbits existed. He had sent from London tame rabbits, perfectly healthy, to his place in the country, and they had contracted coccidiosis in, as he believed, the manner he had just described, and they had died of it. His experience was that young rabbits did not always die from the intestinal form, but sometimes from the hepatic form of coccidiosis. He had experience with young rabbits—seven or eight months old—sent up from Somerset in an apparently healthy condition, which had died within a couple of weeks of arrival in London. The post-mortem revealed rigid and friable intestinal walls, dotted all over with small white spots, and lined by a mucous membrane that resembled sand-paper. The symptoms were profuse diarrhoea and a total loss of appetite. The livers were perfectly sound.

With regard to the danger of coccidiosis to man, he thought that if there were any risk the disease should be very common; but he did not credit infestation in man, nor in cattle—from rabbits; on the contrary, he believed that the parasites were peculiar to the host species, and were not identical. He noticed that this year there had been few wild rabbits about. Was it due to the fact that in consequence of the high price obtained for them last winter farmers were induced to

kill them down? Or was it due to coccidiosis? When in Essex last spring he had seen numbers of dead rabbits lying about, and, although he had not made a post-mortem, he suspected that in these cases death was due to coccidiosis. In conclusion, he again thanked Mr. Buxton, who, he hoped, would settle the question of whether coccidiosis in the bird and in the rabbit was intercommunicable. Mr. Buxton had not referred to hæmorrhagic enteritis, where the intestines were filled with blood. The speaker had seen that both in the rabbit and the bird, and the oocytes were generally very numerous; this occurred not only in young chickens, but also in adult cage birds—not excluding the shrike.

Mr. THOMPSON who spoke next, observed that he attended the meeting, though late, because he felt that he had been instrumental in getting Mr. Buxton to read the paper. He could not say much on the subject of coccidiosis, as a breeder of fancy rabbits and as a veterinary surgeon, he occasionally had carcasses sent to him for his opinion as to the cause of death. He had had several cases in which he had been able to demonstrate, from the yellow pin heads in the liver, the presence of coccidia. In the majority of the cases the outbreak had been very severe, as many as 30 animals being affected, all dying. The symptoms had been a semi-fluid condition of the bowels, and everything pointing to general debility. The age of the rabbits was from one month to ten weeks, but he had not observed the disease in any case where the rabbit was above ten weeks old. The liver showed small yellow patches. A muco-enteritis was present, but he had not seen hæmorrhagic enteritis. Until the last season he had seen practically nothing of the disease. During the last four weeks, his son had lost three valuable covies which were apparently in a normal healthy condition and found death in about six hours. Post-mortem revealed muco-enteritis; no other lesions presented. He was at a loss to account for the enteritis. They were in different pens, and their companions were not affected. The results of microscopic examinations from scrapings of the bowels and faeces were negative. He would ask Mr. Buxton whether coccidiosis of the rabbit was pathogenetic to the cavy. The speaker felt, with Mr. Gray, that the question raised by the paper needed thrashing out, especially in view of the present high value of fancy stock, £80 having recently been refused for a rabbit.

Major HOBDAV pointed out that the rabbit had assumed considerable importance, small animal as it was, during the war. Large rabbitries had been maintained in connection with all the bigger hospitals abroad, and, if only as a change from the good old roast beef of England, the rabbit had proved of the utmost value, indeed rabbit-keeping had become an industry. Some 100 to 150 rabbits provided a change of food in all large hospitals, containing, perhaps, 500 to 600 men, and were much appreciated. With regard to coccidiosis every care was taken in introducing new stock, either French or Italian, to subject them to examination and keep them under observation for ten days to three weeks before placing them in communication with other rabbits. Abroad the people were fully alive to the danger of infection, but, so far as the speaker was concerned, he had not met with coccidiosis. Had they noticed it, it would, of course meant the killing off of the entire stock and making a fresh start. Mr. Buxton's paper would be of great value abroad as well as in England.

Mr. Samson said that many years ago he was consulted respecting Banstead Park, where a large number of rabbits were dying off. He had made post-mortems at intervals of a week or fortnight, and the trouble continued for about three months. He had concluded that tuberculosis was the cause of death, but he did not then know better. The liver was spotted with what he

regarded as tubercular cysts, and he advised killing all the rabbits. They were shot down as closely as possible and quicklime was spread round the coverts and in the warren, which was then shut up for twelve months. He had not heard that the rabbits were afterwards infected. In Carshalton Park the same thing occurred two years later, and the same treatment was adopted, and the place kept closed for two years. Mr. Coleman was living there at the time and, in order effectually to get rid of the mischief, used many tons of lime and shut the place up for two years. There had been no outbreak since.

Mr. H. A. MACCORMACK had met coccidiosis mostly in wild rabbits. Like Mr. Samson, he had confused the disease with tuberculosis until Mr. Gray opened his eyes to the fact that it was coccidiosis. He considered the treatment adopted by Mr. Samson to be the best, and he had always taken that course when consulted respecting infected rabbits. He had seen several cases of what might be called the epidemic form, and his earlier experience had been chiefly with liver cases—little white spots covering the whole of the liver, varying in size from a pin's point to half a pea. Mr. Buxton had said that the hepatic was the chronic form and that the animals did not die so rapidly as with the intestinal form; that the hepatic was chiefly met with in the older animals and the intestinal form in the younger rabbits. In the latter case the course of the malady was very quick and the mortality great. Being interested in the treatment, he noted that Mr. Buxton fell back upon an old remedy, sulphate of iron. He believed, however, that the rabbit would take carbonate of iron more readily than the sulphate—in the form of powder. In conclusion he thanked Mr. Buxton for his very interesting paper.

Mr. DAVIS followed previous speakers in thanking Mr. Buxton for bringing his subject forward.

The speaker had only a limited experience of intestinal coccidiosis. He had met the disease many times in the older wild rabbits, but, until recently, only in the hepatic form. He had during the past few months, however, seen several outbreaks in young rabbits. One he had sent to Prof. Wooldridge, who suggested coccidiosis, and the speaker had found it was so. He had been struck by the fact that the cases of intestinal coccidiosis with which he was acquainted were all of young rabbits, under ten weeks old, and had, further, been impressed by the suddenness with which death supervened. A rabbit owner had told him that he was able to indicate particular rabbits that were going to die, though apparently healthy. Surely enough, animals all right in the morning were dead by night. He did not place faith in treatment, believing that the only thing to do was to clear them out, and after disinfection leave the place vacant a long while.

Mr. McINTOSH stated that he had very little experience of the disease. Some years ago, when acting as Inspector under the Public Health (Scotland) Act, he had seen quite a number of cases in the sheep. The symptoms in that animal corresponded closely with those so well described by Mr. Buxton in relation to the rabbit—a gradual loss of appetite, yellow membranes, pendulous belly, swelling underneath the jaw, frequently diarrhoea and rapid weakness—in fact, symptoms very similar to those seen in the same animal in "fluke" disease. The speaker had seen the liver of sheep so extensively covered with little nodules that its substance was scarcely visible. He had been asked to advise as to treatment, but had never achieved success in the treatment of infected animals. He thought, however, it was possible to stamp out the disease by attention to pastures—where that was practicable. He believed in a dressing of salt or lime, and the fencing off of the infected area for six or, better, twelve months.

From the standpoint of the life history of the parasite he regarded the paper as exceedingly interesting.

The PRESIDENT added his quota of thanks for Mr. Buxton's paper. There were one or two points he would raise by way of supplementing the paper. He would refer, especially, to the existence of diarrhoea in young rabbits affected with coccidiosis, regarded by Mr. Buxton as a constant symptom. Mr. Buxton had not, however, referred to the frequency with which there was no diarrhoea—in which the droppings were quite firm, well formed, and distinctly mucus-coated; a little shred of firm mucus, looking as if it were actually a shred of membrane, could, in some instances, be seen. That, of course, was not common; most frequently the condition of the excreta was soft.

Another notable point was the extreme emaciation, and the fact that, in actually handling the rabbit, the transverse processes of the vertebrae very nearly pierced the skin. Practically nothing was to be felt in the abdomen; although bulky, there were no ingesta. This year he had seen more coccidiosis than he had ever seen before—due, perhaps, to more intensive cultivation of rabbits—and had been struck by the relative infrequency of the hepatic form, and the greater prevalence of the intestinal form, formerly overlooked. In the older books only the hepatic form would be found described. With regard to the lesions, he had not seen one per cent. in the cases of hepatic coccidiosis; and, as had been pointed out by many speakers, the intestinal form had occurred principally in the younger rabbits. Mr. Buxton had emphasised a point of great importance in connection with the periodic examination of the ejecta for coccidia, for the reason that, while it was assumed that microscopic examination would be certain to reveal coccidia if any were present, in certain faeces it might be necessary to make several different examinations before it was certain that coccidia were present, even when, from a clinical examination, there seemed no doubt at all. Among the precautions put forward by Mr. Buxton was one to the effect that contaminated foods should be used only for rabbits known to be affected. The speaker felt, however, that Mr. Buxton's sense of economy had run away with him. Where was the advantage of giving an infected rabbit an increased dose of infection? If the object was to assist the killing, why not kill the rabbit in the first instance, and not waste more food? If, however, the food were positively known to be contaminated, why not use it for other and less susceptible species of animals, if it should be used at all? Positively contaminated food would be small in quantity, and its destruction would be no great loss. Certainly it should not be used for young rabbits, in which coccidiosis was much more virulent than in the adult animal. In relation to the circumstance that young rabbits contracted the disease from the doe, while the latter showed no symptoms of it, this was due to the greater resistance in the adult, and would account for the headway made by the disease at the present time. An apparently healthy doe was bred from, and it was not until the disease had developed in the litter that its existence in the doe was realised. It had then to be decided whether to kill the does or attempt to rear a fresh litter. The decision should rest on the actual value of the doe, which, if not intrinsically valuable, should at once be killed. If of great intrinsic value, particular care should be exercised in regard to droppings; the hutch should be visited frequently during the day, and any faeces at once removed, the food both of the doe and the young being placed where it could not possibly be contaminated by the doe's droppings. Even so, there was danger from the udder; the teats would sometimes be soiled by the doe's excreta. Still, in this way the danger would be at least reduced.

Like Mr. Buxton, Prof. Wooldridge recommended sulphate of iron for treatment, although it was absolutely useless in the case of young rabbits that had begun to show symptoms. If it was to be of any service at all, it

should be used directly coccidiosis made its appearance in the hutches, and be given to all the rabbits, whether showing symptoms or not. Only in that way would the disease be kept in check. When clinical symptoms became apparent, treatment was useless.

Turning to wild rabbits, coccidiosis was met with to a far greater extent than in the tame ones, until recently. It was well known that the disease would exterminate whole warrens. Overstocking of rabbit warrens was the most prolific source of the disease, just as overstocking a farm with sheep and lambs was a prolific source of verminous troubles in that species. When coccidiosis was found in a rabbit-warren the lines laid down by Mr. Samson for the extermination of his suspected tuberculosis could not be improved upon. The length of time that such a warren should be closed down was a matter which Mr. Buxton might aid in determining; it would be interesting to know actually how long, under natural conditions, the coccidium could retain its vitality. The problem was perhaps a difficult one; it was one which had not so far been properly worked out. If the coccidium could only retain its vitality for one season, closing the warren for one season would suffice to get rid of it. If it could keep its vitality for two seasons—and some of the phases of the coccidium were intensely resistant—closing down for one season would be insufficient, but might serve to reduce the disease, especially if accompanied with the free use of quicklime or salt, or both.

Another point of interest was Mr. Buxton's statement that blackhead in turkeys had been proved to be coccidiosis. Of that the speaker had been unaware, and was doubtful whether it had now been positively ascertained. He would ask Mr. Buxton if he had met the condition of blackhead in guinea-fowls, and, if so, whether coccidia had been found? He specifically raised that question, as sometime since he had had guinea-fowls sent to him which presented all the indications of blackhead, such as that known in turkeys. He confessed ignorance as to the cause, and was not, meantime, convinced that blackhead in either species was due to coccidiosis. He had been interested to hear of coccidiosis in cattle setting up red dysentery, due to the same coccidium (the *coccidium zurni*). [Mr. Buxton here remarked that about four years ago they were said to be the same.] There had, Prof. Wooldridge said, been described certain differences between these coccidia which may have justified a separation. Subsequent investigations may, however, have proved their identity. The disease was a matter of great interest to the speaker, and he would conclude by again thanking Mr. Buxton for bringing up the question.

#### REPLY.

Mr. J. B. BUXTON said: He very much appreciated Mr. Gray's remarks, in particular his jocular reference apropos of wild rabbits—that he had discovered that all the wild rabbits he had shot were infected with coccidiosis, for which reason he has assumed that they had been unable to get away as quickly as the others. Mr. Buxton would contend that all the rabbits in the wood were infected, and the survival of some of them was a question of selection; these were probably those in which the disease was chronic. It was frequently found that practically every rabbit coming from a particular area would on examination show the spots to which he had referred in his paper. It was the intestinal form which was more fatal. With regard to dysentery in rabbits, he had found hemorrhagic faeces to be very uncommon, and Mr. Thompson would bear out that statement. The speaker had rather hoped that Mr. Thompson would have referred to a similar pathological picture in the guinea-pig to that which was seen in the rabbit. In these cases however there was enteritis, and the small nodules were found in the liver and sometimes in the spleen, the disease was produced

by *B. enteritidis gartneri*. So far as the speaker knew, the guinea-pig was not very prone to coccidiosis, at any rate, during recent years, when dealing with outbreaks of coccidiosis among rabbits, he had found that guinea-pigs in close contact with the rabbits, and feeding on the same floor, did not show any trace of coccidiosis when killed and examined, not even in scrapings from the intestines. [Mr. Thompson here observed that probably his cases had been true enteritis, but the cases were not very definite; there was one case out of each of three pens, all the others being all right.] Mr. Buxton appreciated Mr. McIntosh's remarks, although he had not considered the case of coccidiosis in the sheep. Prof. Wooldridge had, apparently, found enteritis, but not hemorrhagic enteritis, but the interesting point that there was frequently no diarrhoea in the intestinal form of the disease was outside the speaker's experience. He had not studied the matter closely.

With respect to the feeding of infected animals, he would put the case that adjacent to the affected rabbits there might be a shed containing, say, a sack or two of meal. While he would not suggest that the meal should be given to healthy stock, he would be very loath to burn it. Again, the contamination might be only slight, so that there was justification in running a small risk if the intention was to feed the stuff to animals already infected. He could not endorse Prof. Wooldridge's view that the adult rabbit possessed great resistance to the disease. The fact that an adult rabbit showed hepatic lesions of a chronic nature merely indicated that it had been lucky enough to get through, having had a little more resistance than others, in the earlier stages of the malady. He had found, experimenting with a colony of rabbits infected with the disease, that adult rabbits would die off rapidly if infected. He concurred with Prof. Wooldridge's views as to the use of sulphate of iron; personally, he administered it immediately he perceived any symptoms of coccidiosis in a rabbitry. He would incidentally observe that he had little experience of outside conditions; he had worked within the limitations of a laboratory.

As to blackhead in turkeys, the experiments carried out in this relation were reported in the Report of the Maine Agricultural Experimental Station, in America. He would gladly submit the data to Prof. Wooldridge.

With regard to coccidiosis in cattle, several years ago there was a tendency to think that *C. perforans* was responsible for the intestinal coccidiosis of rabbits and also for the bovine disease. The chief difference between this parasite and *C. oviforme* was that in the division of the protoplasm to form the four sporozoites a portion remained, forming the "residual corpuscle." This however does not appear to be sufficiently constant to warrant such a distinction being made.

The PRESIDENT made a brief reference to the satisfaction manifested at the return of Major Hobday, and expressed the hope that the Society would in the near future benefit by some communication from the major in connection with his experiences during his peregrinations in Europe.

#### RESUMPTION OF MEETINGS.

Prof. WOOLDRIDGE next observed that since hostilities had ceased, with little probability of being resumed the meeting should decide whether the ordinary meetings should be bi-monthly or monthly. Personally he had no strong views; but it would be well if fellows would give expression to their opinions. Owing to the stress of things, attendances had become small, and bi-monthly meetings had been adopted. Notwithstanding that conditions were not likely to be easier for some time, there was a feeling of relaxation, and the fellows might think they could afford the time for monthly meetings. The decision to hold bi-monthly meetings had been

thrashed out, he believed, without any previous notice being given, and perhaps the same course might now be taken with regard to the adoption, or otherwise, of the monthly meetings.

The discussion at this point became informal, the following gentlemen expressing their opinions briefly. Mr. Buxton suggested that the bi-monthly meetings should continue until the return of Fellows now out of England. Mr. Davis did not think there should be a meeting in the early days of January, but meetings might be held in February, March, and April. He also raised the question of a dinner. Mr. McIntosh felt that the Society should resume the monthly meetings at as early a date as possible. Many important matters concerning the profession needed consideration, and monthly meetings would largely assist in arranging such matters. With the improbability of the war breaking out again, he thought the profession should be active and watchful. He would suggest that monthly meetings should be resumed with the beginning of the new year. Mr. MacCormack agreed with the last speaker, but the beginning of January is too early, in view of the difficulty of getting papers. The present meeting was a good one, but only three or four of the Fellows were not constant attendants. The others had been turning up month after month during the war, and much honour was due to them for so doing. He thought the monthly meetings should be resumed when peace was declared, when from all parts of the Dominions the men would have returned from active service. The President, referring to Mr. Davis' suggestion for a dinner, recalled that Mr. Almond had suggested at an earlier meeting that a dinner would not be out of place, and since it was necessary to eat there could be no objection to adding social intercourse. Perhaps the adoption of a double principle would commend itself, namely, commencing with a dinner to set the ball rolling again, and proceeding subsequently with monthly meetings.

Further discussion ensuing, some members were in favour of the earliest possible date, others thought February next a suitable date. Finally, Mr. Almond proposed that the Fellows should have a dinner in February, 1919, and that the monthly meetings should afterwards be resumed. Mr. Davis seconded the proposal, which was carried by a large majority. The general arrangements and the question whether ladies should be invited to the dinner were left to the Dinner Committee.

The SECRETARY proposed that the Dinner Committee should consist of the President, the Treasurer, Mr. McIntosh, Mr. Jack Willett, and himself.

The proposal having been duly seconded and put to the meeting was unanimously carried.

A general discussion followed regarding the position of veterinary students serving in the army, and the desirability of urging their early release.

Mr. MCINTOSH pointed out that the Royal College of Veterinary Surgeons already had the matter under consideration.

The PRESIDENT believed that the teaching colleges and also the Council of the Royal College were, in fact, pushing the matter with all vigour, but no harm could result from submitting a resolution to the Royal College if they thought it worth while.

Mr. SHEATHER proposed, Mr. Buxton seconded, and Mr. Almond supported the following resolution, which was carried unanimously:—

"That the Central Veterinary Society intimates to the Royal College of Veterinary Surgeons that it wishes to support and press the application that is being made for the release of students on active service, in order that they may resume their studies at the earliest possible date."

The proceedings terminated with the passing of a vote

of thanks to Mr. J. B. Buxton for the paper he had read. Mr. Gray, who supported the vote, remarked that he hoped Mr. Buxton would, on some future occasion, present the Society with a paper on Coccidiosis in Poultry, of which there was less known than in the case of rabbits.

HUGH A. MACCORMACK, Hon. Sec.

### THE ROYAL COUNTIES V.M.A. AND THE COUNCIL R.C.V.S.

To the Editor of "The Veterinary Record."

Sir,—At the discussion on the Council by the Royal Counties V.M.A., the following views were expressed:—

1. New and vigorous blood and broadened minds are wanted on the Council. 2. Some members of Council only attend one or two meetings a year. 3. Some of the present members are head and shoulders above the others, and these few lead the remainder—which does not tend to efficiency. 4. When a member of Council objects that nothing much is done at a Committee meeting, or brings forward special matters for attention, he is put on such-and-such Committees to "shut his mouth." 5. The schools are over-represented, and rule the profession. 6. No interest of the Council in things nearest to the heart of the general practitioner. 7. The Council seemed to be divided into two camps—not recently, but formerly.

I am a newcomer on the Council, after years of residence abroad, so perhaps my views are less biased in consequence. Taking the above paragraphs by numbers, it seems to me that:—

1 and 2. New blood is undoubtedly wanted to replace those members who only attend one or two meetings a year, and also those who, when they do attend, never get up and say anything original, much less try to do anything, and finally grumble at everything that is done.

3. Some of the present members are head and shoulders above the others, and these few lead the remainder, but the loss of efficiency, if any, might reasonably be considered the fault of "the remainder."

4. A member is not put on a Committee to "shut his mouth," but to encourage him to do something.

5. There are 32 members of Council, of whom 5 only are connected with the schools. This is hardly over-representation. An Examination Committee composed of members of Council with no school representative on it would have a stiff time, say, in revising our curriculum, a matter which must shortly be taken up.

6. The remedy is to get new members, general practitioners or otherwise, who will take the place of the many inert members now on the Council.

The Associations, for the coming elections, are quite entitled to put forward capable men as their official candidates, and vote for them, and when they get in give them a programme to carry through.

Such would be a constitutional method, but long-range "sniping" of the above description will not make for the good of the profession.

Let us have unity and progress.—Yours, etc.

S. H. GAIGER, F.R.C.V.S.

The report of the Royal Counties V.M.A. in your last issue of *The Veterinary Record* must be of very great interest to the profession at the present time, as a very fair criticism was given of the present Council of the Royal College of Veterinary Surgeons.

The President of the Royal Counties V.M.A. said: "New blood was necessary, that men who had gone out and done their bit, who have seen things and had their

minds broadened, are the men we want on the Council if we are to have vigorous treatment in the profession." "Eight retire each year and are usually nominated by their noble selves."

Now with the above remarks I agree in their entirety, for the simple and obvious reason that if one judges a body by the results they have achieved the most of the present members on the Council of the R.C.V.S. might with advantage to the profession retire of their own accord, and make room for younger and more energetic men who are so badly needed.

Preferential treatment in electing new blood ought to be accorded to men who have served their country; but intermingle with them a few energetic practitioners who know the needs of the profession, and who have only the interests of their profession at heart.

Hitherto the profession has been run by the schools, and with what results? Take, for instance, the position of practitioners under the Military Service Acts, and compare them with the medical or dental professions. The former always had its own tribunal, the latter obtained its tribunal long before we did, and we would never have had a Veterinary Tribunal if it had not been for the energies of one man on the Council, and he is not a representative of the schools; but he recognised the necessity of equivalent treatment being given to all members of the profession, because he was practical in his views—as distinct from the ultra scientist who may be a good man in delivering lectures, but totally incapable of guiding the destinies of the clinician.

As a further example of the administrative capabilities of the ultra scientist take the recent examinations, published in *The Veterinary Record*, Dec. 28, 1918. We find:

5 men	got qualified in	London.
2 "	"	" Liverpool.
1 man	"	" Glasgow.
4 men	"	" Dublin.

Total 12 men; yet I understand that Examiners have had to travel to these places of decentralisation. Why? The only answer I can give is, The schools decide these things, and obviously do so for their own convenience, instead of studying the funds of the R.C.V.S., which we all know are sadly depleted. If all the students had been centralised for the examinations in December last just think what the R.C.V.S. would save in expenses.

The election of the Council has been conducted year after year on the same old lines. Men whose names have been a household word in the profession have been put up and, in the ordinary course, elected; once there, they appear to get grooved with their brethren, and the next thing they are taught to do, is to become subservient in the execution of their ideas to older members.

The remarks made by Mr. Coleman, a member of the Council of the R.C.V.S., at the Royal Counties V.M.A.: "At the present time the majority of the Council followed the lead and supported about four men, whatever they said." Well, I have been of that opinion for some time, and it only convinces me of the weakness of these men, many of whom I know personally.

The time has now arrived when the profession must cast aside its lethargy, as many difficulties will arise in the future which will be overcome only by successful practical men: the ultra scientist has given us his best and convinced us that he has been a failure in running the profession, whose wants he obviously knows nothing about.

My experience of the profession is that most of the successful members have preferred to abstain from entering into its politics. Problematical as this may appear, it is capable of solution, a busy life and no time to spare is most probably the cause. Nevertheless it is highly regrettable, as these are men who are needed and who understand the wants of the practitioners, who after all comprise the greater part of the profession.

By all means let us have the Royal Army Veterinary Corps and the Board of Agriculture represented on the Council, and, say, two schools, whose representatives ought to retire annually to allow two members from other schools to be elected. Under these circumstances the schools would be adequately represented and we might possibly obtain a chance of seeing the profession running a successful course, more especially if young, energetic, and enthusiastic men were prevailed upon to stand for election, to complete the remaining numbers of members on the Council.

We have had far too much legal administration from the present body, who apparently seem totally ignorant of the things nearest the heart of the general practitioner, in fact I will go further, and say that the present Council seem to have no interest in the profession whatever except in the administration mentioned.

A lead is undoubtedly necessary from the council in interesting themselves in matters which appeal to the profession, then, and not until then, shall we obtain the enthusiastic support of the men best fitted for the council, namely the successful practitioners, as we have already had enough proof to convince us that the ultra scientist is a failure in this respect.

I therefore appeal to all members when voting to support only practitioners who have no axes to grind, and whose interests are entirely professional; and to eliminate from your minds, once and for all, those who study personalities prior to professional interests. If you carry this in your mind when the next election takes place, and remember it at future elections, we shall, I hope, have the proper representatives on the

council in the future, many of whom at the present time are, might I say almost "unknown" and "unseen."

Remembering the quotation.

"Full many a flower is born to blush unseen,  
And waste its sweetness on the desert air."

Yours faithfully, REFORM.

#### BOARD OF AGRICULTURE AND FISHERIES

Replies to The Secretary. WHITEHALL PLACE,

Quote No.—A. 3163/1917.

LONDON, S.W. 1.

Telegraphic Address—

30th Dec., 1918.

Agrif. Westrand-London.

Sir,—In view of the probability of some dogs being smuggled into this country during the period of Demobilisation of the various Expeditionary Forces with a consequent risk of the spread of rabies, I am directed by the President of the Board of Agriculture and Fisheries to ask your assistance in suggesting to veterinary practitioners the desirability of bearing this in mind in the course of their practices.

The Board are receiving so large a number of applications for licences to land dogs that available accommodation for quarantining dogs will in the near future be insufficient; any veterinary practitioner in the position to quarantine one or more dogs might therefore communicate with the Board.—I am, Sir,

Your obedient Servant,

W. H. CHAMBERLAIN,

for Secretary.

The Editor "Veterinary Record."

## ARMY VETERINARY SERVICE

War Office, Dec. 30.

The following is a continuation of Sir D. Haig's Dispatch of the 8th November, 1918, submitting names deserving of special mention:—

Maj. and Bt. Lt.-Col. (actg. Lt.-Col.) J. J. Aitken, D.S.O.; Capt. D. Blyth (S.R.), attd. 8th D.A.C., R.F.A.; Temp. Capt. F. L. Clunes, Comdg. 18th Vet. Evac. Stn.; Temp. Qrmr. and Capt. C. Cooke, 9th Vet. Hosp.; Hon. Lt. (temp. Maj.) H. A. Crowe; Temp. Capt. L. A. Donovan; Temp. Capt. J. Dunn; Temp. Capt. A. Gofton, F.R.C.V.S., 19th Vet. Hosp.; Capt. D. C. Greene; Temp. Capt. R. W. Hadfield, 33rd Mob. Vet. Sec.; Temp. Capt. J. E. Hanna, M.C.; Temp. Capt. R. L. L. Hart (E. Afr. Vet. Corps.); Temp. Capt. J. Hill, attd. 38th Army Bde., R.F.A.; Temp. Capt. S. Hirst, attd. 117th Bde., R.F.A.; Capt. P. Howard (S.R.), Comdg. 15th Vet. Evac. Stn.; Temp. Capt. C. A. Hutton, 1st Vet. Evac. Stn.; Capt. J. J. G. Keppel (S.R.), attd. 29th Mob. Vet. Sec.; Temp. Capt. J. MacFarlane, 49th Mob. Vet. Sec.; Temp. Capt. C. O. Machonachie, M.C.; Temp. Capt. H. E. McGee, Comdg. 23rd Mob. Vet. Sec.; Temp. Capt. B. A. McGuire; Temp. Capt. H. V. M. Metivier, 40th Mob. Vet. Sec.; Temp. Capt. J. C. Miller; Temp. Capt. H. K. Roberts; Capt. C. J. C. Ryan, 13th Mob. Vet. Sec.; T. Capt. A. R. Smythe, 31st Mob. Vet. Sec.; Capt. P. S. Thierry, attd. 317th Bde. R.F.A. (T.F.); Capt. P. J. Turner, attd. 5th D.A.C., R.F.A.; Temp. Capt. J. B. Walker; Temp. Capt. J. H. Yates, 28th Mob. Vet. Sec.

R.A.V.C. (T.F.)

Capt. R. Bickerton, 2/1st N. Mid. Mob. Vet. Sec.; Capt. A. C. Burton, 14th Vet. Hosp.; Capt. D. R. Crabb, 2/1st W. Rid. Mob. Vet. Sec.; Capt. (actg. Lt.-Col.) H. C. Jagger; Capt. E. E. C. MacLachlan, 1/1st Low Mob. Vet. Sec.; Capt. J. Martin; Capt. (actg. Lt.-Col.) J. McArthur, 14th Vet. Hosp.; Capt. F. J. Richmond.

CANADIAN A.V.C.

Capt. N. Beaver, attd. 8th Can. Inf. Bde.; Capt. (actg. Maj.) S. C. Richards, Can. Vet. Hosp.; Capt. W. A. Robertson, attd. 12th Can. Inf. Bde.; Vet. Sgt. W. Kennedy, 320865.

AUSTRALIAN A.V.C.

Maj. T. H. Hankin; Capt. J. Legg, 3rd Mob. Vet. Sec.; Capt. W. S. T. Morgan, attd. 4th Aust. Div. Train.

## THE ORDER OF ST. MICHAEL AND ST. GEORGE.

The King has been pleased to give directions for the following promotions in, and appointments to, the Most Distinguished Order of Saint Michael and Saint George, for services rendered in connexion with military operations in France and Flanders. Dated January 1, 1919:—

C.M.G.

Maj.-Gen. J. Moore, C.B., F.R.C.V.S.

## ORDER OF THE BRITISH EMPIRE.

The King has been pleased to give orders for the following promotions in, and appointments to, the Most Excellent Order of the British Empire, for valuable services rendered in connexion with military operations in France and Flanders:—

O.B.E. (Military Division).

Capt. (actg. Maj.) W. Ascott (T.F.); Capt. (actg. Maj.) J. S. Bowden (T.F.); Temp. Lt. (temp. Maj.) H. A. Crowe; Maj. P. W. Dayer-Smith (T.F.); Capt. (actg.

Maj.) R. A. Gooderidge; Temp. Capt. J. Hill; Capt. (actg. Maj.) S. E. Holmes (S.R.); Capt. (actg. Lt.-Col.) H. C. Jagger (T.F.); Capt. (actg. Lt.-Col.) J. McArthur (T.F.); Temp. Capt. B. A. McGuire; Maj. (temp. Lt.-Col.) A. W. Mason, (retd. T.F.); Maj. W. W. R. Neale; Temp. Maj. (actg. Lt.-Col.) E. W. Parks (T.F.); Temp. Capt. J. B. Walker.

CANADIAN A.V.C.

Capt. (actg. Maj.) S. C. Richards; Capt. W. Robertson.

AUSTRALIAN A.V.C.

Maj. R. M. Hore.

## PROMOTIONS AND OTHER REWARDS.

War Office, Jan. 1.

The King has been pleased to approve of the following rewards for distinguished service in connexion with military operations in France and Flanders. Dated Jan. 1, 1919:—

TO BE BREVET MAJOR.

Capt. (actg. Maj.) F. B. Sneyd (S.R.); Capt. (temp. Maj.) W. H. Taylor.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Dec. 30.

## TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Maj. R. C. Thompson (late Maj., Yorks Dgns) reverts to ret. list, on attaining age limit (Dec. 31).

Capt. G. E. Henson to be actg. Maj. while empld. as D.A.D.V.S. (Oct. 4).

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1918:—

W. F. Barrett, Brockley, S.E.	£1	1	0
R. J. Hickes, Market Weighton	1	1	0
P. J. L. Kelland, Bd. of Agriculture	1	1	0
M. Twomey, Macroom, Co. Cork	1	1	0
Previously acknowledged	1124	6	11
	£1128	10	11

## Prosecution under the V. S. Act.

Henry John Smith (50), ostler, Llanhilleth, was summoned at the local court on Tuesday 31st ult. for unlawfully describing himself as a veterinary surgeon.

The evidence for the prosecution was that the defendant, at the request of several people in the district, examined a number of pigs, and said they were suffering from influenza. He prescribed for them and was paid for it. He supplied powders around which he had used labels on which was printed "Smith, veterinary surgeon, Usk." The labels it transpired, belonged to his late father, who had resided in Usk.

Defendant said he had worked at a colliery for four years, and had never made himself out to be a vet. He had told people he was not a qualified man.

The Chairman (Dr. E. Ryan) said the magistrates thought he had been sailing very near the wind, but there was no proof that he had made himself out to be a veterinary surgeon. The case, therefore, would be dismissed.—*South Wales Echo*.

## OBITUARY.

HERBERT SPRINGETT, M.R.C.V.S., Sydendam, S.E. 26.  
 Graduated, Lond: May, 1863.

Mr. Springett died Dec. 28th, 1918.

## Personal.

TOWNSON.—On 29th Oct., 1918, at Darwin Harbour, Falkland Islands, the wife of Vet.-Lieut. H. W. Townson—a son.

Mr. F. E. PLACE, M.R.C.V.S., Government Veterinary Lecturer, Adelaide, S. Australia, met with a serious accident at the Roseworthy Station recently. He was alighting from a trap when a passing motor cycle startled the horses, which moved forward and caused him to fall heavily on the ground. So soon as possible Mr. Place was conveyed to Adelaide, and taken to the Kent Town Private Hospital. An X-ray examination revealed that he had broken a hip in two places. In the circumstances some months will probably elapse before he can resume his duties, a fact which, together with his unfortunate mishap, will be keenly regretted by the farming community. The greater part of his time during the last few years has been devoted to lecturing and demonstrating before members of the many branches of the Agricultural Bureau, by whom he is held in the highest esteem, and acknowledged to be one of the most popular and practical lecturers ever associated with the Department of Agriculture.

[The date of the accident does not appear, as only a fragment of the newspaper reached us; but the envelope bears post mark Adelaide, Nov. 21.]

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1592.

JANUARY 11, 1919.

VOL. XXXI.

## SCHEDULED DISEASE IN 1918.

With the report of December 28th, the Board of Agriculture completed its returns of scheduled disease for 1918; and we can review a year's work which, despite all difficulties, has been largely successful and highly creditable.

Three diseases show considerable decline. Anthrax has 245 outbreaks against 421 in 1917, swine fever 1407 against 2104, and sheep scab 351 against 543. The improvement in sheep scab becomes more marked from the fact that 244 of the 351 outbreaks occurred in the first six months of the year. We seem to have done so well against these three diseases as we could even have hoped.

Only three outbreaks of foot-and-mouth disease, involving 14 animals, occurred during the year; and all were close together. The first was late in September, the other two in October. It seems that these occasional visitations cannot be avoided at present; the great point is that we are able to subdue each as it comes. We are doing as well against this disease as could reasonably be expected.

Other diseases show the inevitable results of war conditions. By far the most serious position is with regard to rabies. Over a hundred cases have occurred since the beginning of September, and fresh ones are still being reported every week. So far, the disease has been successfully confined within the area in which it first appeared; and there is no doubt that the Board will be able to deal with the existing amount of it in time, if only fresh importations can be prevented all over the country. We all know how it originated, and recognise the only means of avoiding further heavy infection of the kingdom. The most pressing need just now is to teach the public the danger of importing dogs, which the Board of Agriculture is trying hard to do; and many veterinary surgeons are in a position to give valuable help in this direction.

Glenders, for the first time for many years, has increased a little; parasitic mange has increased a great deal. The cause in both cases is war conditions; and in both we may expect further increases next year.

This leads to the last and most important consideration. We are now commencing a time which will be more dangerous, so far as the spread of contagious disease is concerned, than the period of actual fighting. The danger will be materially increased by the chaotic conditions which now prevail over so large a part of Europe; and no one can say how long those will continue. But, even if order is restored upon the Continent much more quickly than at present seems likely, the dangers of importing disease will be greater than they ever were during the war. It is fortunate for us that the Board's veterinary staff is efficient and well led; for it will need all its resources, and all the assistance that the profession can give, in the time that lies ahead.

## OBSERVATIONS ON NEW RABBIT DISEASE AND ITS RELATION TO COCCIDIOSIS.

By E. R. SMYTHE, M.R.C.V.S., Falmouth.

Since utility rabbit keeping has become popularised in this country, attention has been drawn to the very high rate of mortality occurring among young rabbits. The subject has of late received a considerable amount of attention from veterinary surgeons and others, and the losses have been universally attributed to the effects of coccidia, present in the intestinal walls and the liver.

It is the intention of the writer to show in this article that coccidia alone are but rarely responsible for death, that these protozoan parasites are common to almost every rabbit, and that the actual cause of the disease is the presence of a specific organism in the blood or in various organs, being deposited therein by the blood-stream.

### THE PREVALENCE OF COCCIDIA AMONG RABBITS AND OTHER ANIMALS.

Seeing that coccidiosis has been blamed for the wholesale destruction of warrens and pedigree studs, it has been inferred that there existed rabbits which were free from coccidia as well as others infested by them. Moreover, it has been urged that an infested doe is incapable of rearing healthy youngsters, and that such an animal introduced into a warren would necessarily lead to disease and

mortality among the previously healthy stock. It has even been advised in the press that the faeces of all newly purchased animals should be examined microscopically, and that all does, even when apparently healthy, in which coccidia were demonstrable, should be rejected.

We have examined the faeces of probably hundreds of rabbits of all ages, kept under varying conditions of domestication or living wild in the natural state. Some of these tame rabbits were from so-called "infected" stock; others were apparently perfectly healthy. In no case have we failed to detect coccidia upon microscopical examination.

In some instances, the parasites were present in far greater numbers than in others, but their relative frequency had apparently no bearing upon the rate of mortality; in fact, we have frequently demonstrated the presence of enormous numbers of coccidia in "healthy" young rabbits from studs in which there was no mortality or history of such; whereas in warrens or hutches, where 95% of the young rabbits invariably died, frequently very few coccidia could be detected.

\*The earliest age at which we have found coccidia in the faeces is one week.

From our investigations we conclude that practically, if not absolutely, every rabbit harbours coccidia, and that they are natural parasites. Although they produce characteristic lesions in the intestine and liver, and sometimes in the respiratory tract, these are very rarely sufficiently grave to cause marked illness or death.

In all probability the same remarks regarding the presence of these parasites apply to the great majority of herbivorous animals. They can be detected in the faeces of nearly all, if not all, ruminants. In bovine faeces they are plentiful, and although they have been credited with causing dysentery in calves, it is more probable that they render the intestinal wall less resistant to the attack of other organisms.

Although we have made no investigation, it is also possible that "white diarrhoea" of chickens and young turkeys may be dependent upon similar causes, although in our experience coccidia can but seldom be detected in the faeces of healthy birds.

**Symptoms.** For the sake of clearness we will now briefly describe the symptoms occurring in young rabbits affected with the disease which has up to the present been confounded with coccidiosis. The disease may assume an acute, subacute, or chronic form. It may appear in rabbits a fortnight old, more frequently it develops at the age of five or six weeks, and but seldom after ten weeks.

The *acute form* is most common in rabbits during the first six weeks of their lives. As a rule one or more are found dead in the morning without having exhibited signs of previous illness. Death is in nearly all cases preceded by convulsions lasting from a few minutes to several hours.

*Subacute and chronic types.* Here the animals are lethargic, and sit huddled up, with the eyelids half closed, and exhibit a staring, "open" coat. The appetite diminishes and rapid emaciation sets

in. Diarrhoea may or may not be present; sometimes it is profuse and watery. In the majority of subacute cases death occurs suddenly after a convulsion. In those instances in which the chronic form appears, the abdomen enlarges whilst the loins waste, so that a characteristic "pot-bellied" appearance results. Recovery is very rare.

It is interesting to note that in certain districts where calves suffer from "coccidiosis," they frequently develop convulsions which precede death, and it is possible that the same causes may operate in these animals as in the rabbit.

**Post-mortem appearances.** *Acute form.* Usually *nil*. When coccidia are present in large numbers the characteristic liver lesions may be observed, but, in our experience, these may be met with in nearly all rabbits. Lesions due to invasion of the bile ducts by worm embryos are almost equally common.

Apart from lesions due to these causes, careful examination will usually detect one or more pale areas in the liver tissue. These will be discussed later. In addition, in a few cases one meets with a diphtheritic deposit upon the mucous membrane of the large intestine.

*Subacute cases.* The bowel, when washed and held to the light shows numerous pits or ulcers, filled with a gritty or cheesy substance. The appearance may be as though the bowel were sprinkled with fine sand.

*Chronic form.* The bowel wall, liver, and particularly the spleen, and in a few cases the pleura and peritoneum, show numerous nodules, somewhat resembling those of glanders.

**Etiology.** As stated before, we have formed the opinion that the mortality in young rabbits is *not* due to the presence of coccidia alone, but is brought about by a specific organism.

The bacillus, which is always in evidence in these cases, ranges from 2 to 5 *microns* in length and is about 1 to 5 *microns* in breadth, including its envelope, which is well-marked and comparatively thick. In appearance it somewhat resembles the anthrax bacillus. The ends are square-cut and it commonly occurs in pairs or in threes. It stains readily with methylene blue, but not by Gram's method. It is to be found in great numbers in the ulcers in the walls of the large intestine, and although innumerable organisms are present in the intestine, by washing the bowel and subsequently scraping the surface of an ulcer the bacilli are obtained in great numbers, almost free from adventitious bacteria. The diphtheritic membrane, when present on the surface of the intestine contains, besides coccidia, innumerable organisms of the type described.

During the convulsions which characterise the acute form of the disease, a condition of septicæmia may be demonstrated by microscopical examination of blood films. The bacilli are in some cases very plentiful but usually when viewed with a 1/12 in. oil immersion lens, from one to three may be observed to each field of the microscope. They may also be found in the substance of the spleen, but, are more plentiful in the one or more localised light-coloured patches, before mentioned as occur-

ing in the liver. The largest number of bacilli are to be found in the brain substance, when this organ has been removed directly after death. This applies only to those cases in which convulsions have occurred.

In the few instances in which by careful nursing, life has been prolonged for a few weeks, we have found that the nodules, before mentioned have developed throughout the abdominal organs. The lungs themselves do not appear to have become infected, although the pleura frequently shows evidence of it. The whole appearance has suggested either tuberculosis or glanders. The nodules however showed no true caseation, but were composed of a centre of creamy pus surrounded by an inspissated layer. The pus, upon microscopical examination, appeared to be a pure culture of the bacillus described.

The disease therefore appears to correspond with the pseudo-tuberculosis of rabbits described by Pfeiffer, but assumes an acute septicæmic type. It is apparently introduced into the system by means of infected foodstuff. Immunity appears to be acquired with adult age.

It appears probable that bacilli gain admission to the blood stream through the liver, which they reach via the bile ducts, possibly in company with coccidia; or that they enter the vessels or lymphatics through the intestinal walls. A very distended condition of these vessels associated with swelling of the neighbouring glands, occasionally met with on post-mortem examination, points to the lymphatic system as being the principal channel of infection. Coccidia may assist the bacteria to penetrate the bowel wall, but the typical ulceration present in many cases appears to be due to the action of the bacilli.

The actual cause of death in acute cases is in all probability embolism or hæmorrhage occurring in the brain or its membranes. The post-mortem appearances usually point to one of these conditions. Coccidia apparently have little effect on the health of rabbits unless they are present in sufficient numbers to almost totally destroy the functions of the liver. They seldom cause death, but may be responsible for a condition of chronic emaciation in adult or half-grown rabbits.

#### BREEDING AND FEEDING EXPERIMENTS.

To obtain further proof of the minor part which coccidia play in producing mortality in young rabbits, the writer conducted the following experiments. Ten does, each showing numerous coccidia in the faeces, were bred from. The does throughout, and the young when sufficiently advanced, were fed on bran and leaves of cabbage and other green stuff from one particular source. The average mortality among the young stock was 95 per cent. The cases were all of an acute type, death being preceded by convulsions, at ages varying from three to six weeks. A few of the same does and the surviving young does were removed to other premises and bred from. Coccidia were still as numerous in the faeces. The food now consisted of bran and grass or other hedge plants. Those does which

had formerly lost practically the whole of their youngsters, and the surviving young does bore litters which in their turn harboured coccidia, but the mortality from disease was now reduced to nil.

These experiments indicate that the disease is conveyed by infected greenstuff or that certain premises harbour the organism, which is apparently pathogenic only to young animals. It is also interesting to note that a definite period usually elapses in acute cases between ingestion of infected greenstuff and the occurrence of symptoms. Several rabbits of the same litter invariably developed convulsions on the same day, and in nearly every case on the third or fourth day after receiving the infected leaves.

#### PROPHYLAXIS.

The essential factor is the avoidance of leaves and fodder from certain infected sources. Hedge-plants are to be preferred to vegetable leaves. Cleanliness and the isolation or destruction of infected youngsters is imperative.

We have seen satisfactory results follow the daily administration of Sodium sulphocarbolate, dissolved in milk, grs. ii to each young rabbit.

#### TREATMENT.

Destruction is to be advised. Outbreaks of diarrhoea can be controlled by administration of Creosote  $\frac{1}{2}$  minim. for a rabbit of six weeks, combined with a little catechu.

Possibly, were the investigation carried further, an immunising serum might be prepared for use in valuable stock.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### POLYVALENT SERUM OF LECLAÏNCHE AND VALLÉE IN THE TREATMENT OF CANINE DISTEMPER.

Bresson gives an account of this in the *Revue générale de Médecine Vétérinaire* for 1917. His view of distemper is as follows. In veterinary pathology, distemper is perhaps the type of infections in which the secondary action of common microbial agents exceeds in gravity the primary action of the specific agents. The filtering virus of Carré, the causal agent of distemper, appears, when alone, to be easily tolerated by the animal. The clinical signs, the serious symptoms, and the mortal lesions observed in this disease are caused by the ordinary microbes of suppuration (Streptococci, staphylococci, etc.), which discharge their pathogenic rôle secondarily, by favour of the effects of the filtering virus. For this reason, leaving on one side all symptomatic treatment, the management of distemper is reduced to combating and preventing the secondary action of pyogenic microbes.

Starting upon this basis, and proceeding solely upon the principle of the great importance which secondary pyogenic infection possesses in distemper, the author, upon the advice of Leclainche and Vallée, has used the polyvalent serum prepared by these workers. All his distemper cases were treated systematically for five days with a daily subcutan-

ous injection of from 40 c.c. to 50 c.c. of polyvalent serum. Two dogs were treated with intravenous injections of 30 c.c. without any particular result. At the end of five days the dose was reduced to 15 c.c. every two days. The injections were made at different sites (neck, shoulder, flank), and without special antiseptic precautions.

In addition to the serum the author employed the following symptomatic treatment. Upon the entry of the dogs into the infirmary he gave an emetic of Syrup of ipecac. and followed this up with tonic injections of caffeine, a milky diet, rice water, powdered carbon, and alcohol.

From his experiences the author concludes that the polyvalent serum, used in massive doses from the time of the appearance of the first symptoms, has preserved the animals from pyogenic complications, and that, used upon animals bearing manifest secondary lesions, it combated the infection by the pyogenic agents causing these lesions, and enabled a large number of such animals to be saved.

W. R. C.

#### VESICULAR STOMATITIS IN CATTLE.

ADOLPH EICHORN.—*Amer. Jl. Vet. Med.*, 1917.

The United States Bureau of Animal Industry received rather alarming reports from Kansas and neighbouring parts that a disease existed among the livestock, particularly among cattle and horses, closely resembling foot-and-mouth disease. On arriving at the scene of the outbreak Eichhorn observed that the buccal lesions resembled those of foot-and-mouth disease so closely that a differentiation was almost impossible. In early cases typical vesicular formations with an accumulation of lymph were found. These vesicles ruptured readily, leaving a surface similar to that seen in foot-and-mouth disease. The lesions were not confined to any part of the mouth, the tongue was affected in about 50 per cent. of the cases, the dental pad was rather more frequently affected; the other parts of the buccal mucous membrane showed lesions varying in frequency. The regenerative process progressed very rapidly, the only difference from foot-and-mouth disease being that in some cases the eroded parts were covered with a thick gelatinous pseudo-membrane.

Inoculation tests.—Three calves were inoculated by scarification and five others, kept in another isolated pen, were inoculated intravenously with material from the lesions. The scarified calves developed lesions on the dental pad in 48 hours, but these were not quite typical in appearance. The calves inoculated intravenously remained unaffected. Interdigital inoculation of five pigs gave negative results. Likewise horses inoculated by rubbing infected material on the tongue showed no lesions on the third day and so the tongue was re-inoculated by scarification. "One of the horses on the third day developed a vesicle on the dorsum of the tongue and, as in the successful transmission to horses in Washington, on the following day an expansion of the disease was observed affecting almost the entire surface of the tongue."

The disease differed from foot-and-mouth disease in the following respects:—(1) the transmissibility of the disease to horses from cattle and the failure to infect pigs, (2) the absence of foot lesions in infected and exposed cattle, (3) the appearance of newly-formed vesicles after the commencement of the healing process in some cases, (4) the immunity of a large proportion (up to 60 per cent.) of exposed animals in some centres, and (5) the temperature was not observed to rise over 103° F.

#### A TREATMENT OF EPIZOOTIC LYMPHANGITIS.

BRINGARD, *Bull. Soc. Cent. Méd. Vét.*, 1917.

In this article the author describes a method of treatment adopted by him with successful results over thirty years ago in Algeria. His observations led him to conclude that the appropriate treatment consisted in the surgical extirpation of the swollen lymphatic vessel, or its destruction by means of some procedure acting directly on the interior of its lumen. The drugs employed failed to give satisfactory results. The removal of the lymphatics by means of a bistoury is attended with grave risks on account of the damage done to the surrounding tissues, and of secondary infection.

The instruments thus used by the author consisted of iron rods about 18 inches long and about the thickness of a lead pencil, provided with a wooden handle at one end. These rods heated white hot served to cauterise the whole of the interior of the lymphatic. The operation is easily performed; the horse is cast so as to expose the affected lymphatics. If the lymphatic is no more than about 9 inches long one excises the bud on the side away from the lymphatic gland and then inserts the heated rod into the exposed orifice and passes it along the interior of the channel up towards the centre of the lymphatic gland. When the affected lymphatic is longer the process is repeated two or three times by passing the rod each time from a distal bud to another situated more centrally. The rods may be curved in order to follow tortuous lymphatics. Cases where the buds are not connected by means of apparent lymphatics are inoperable by this method, but such cases are very rare, and do not exceed 5 per cent. During the first week after the operation an abundant suppuration takes place leading to the shedding of the cord and glandular congestion.

A 10 per cent. solution of tincture of iodine is afterwards injected into the channel. It is claimed that cures can be effected in four to five weeks in cases of horses refractory to all other methods of treatment.

Details are given of eight cases occurring in the French army; on these the author had the opportunity of again testing his method of treatment. The results again proved its efficacy as all the horses were cured in a comparatively short time.—*Trop. Vet. Bullet.*, Sept., 1917.

#### AN ITALIAN METHOD OF ANTI-RABIC TREATMENT.

CLAUDIO FERMI, *Ann. d'Igiene.* 1916.

The method of rabies vaccination evolved by Fermi at Sassari, Sardinia, is briefly as follows.

The vaccine consists of a 5 per cent. emulsion of a potent fixed virus, carbolised 1 per cent., direct from the rabbit or dog. The brain instead of the cord is used, as the former was shown to be more active. The anti-rabic serum is obtained by hyperimmunising horses, using the above vaccine as antigen. The sero-vaccine consists of 1 part of serum and 2 of vaccine, carbolised 1 per cent. The method of treatment consists in the administration of sero-vaccine for the first 5 to 10 days followed by the injection of the vaccine alone up to the 25th day. The mortality from rabies following this treatment was calculated to be lower than that following treatment according to the methods employed by Högyes, Bernstein, and Remlinger. Advantages claimed for the vaccine and sero-vaccine are that they can be preserved for long periods sterile and potent in sealed tubes, can be transported over any distance for use, do not inconvenience the patient, and set up an immunity immediately in the case of severely bitten patients.

The new Italian method is stated to have been substituted in British India for a number of years for the Pasteur and Högyes methods on account of the superior results obtained.—*Trop. Vet. Bullet.* Sept. 1917.

#### MIDLAND COUNTIES VETERINARY MEDICAL ASSOCIATION. [NATIONAL V.M.A.—NORTHERN BRANCH.]

The quarterly meeting was held at the Grand Hotel, Birmingham, on Thursday, November 28th, 1918, the President, Mr. John Malcolm, occupied the chair. There were also present: Messrs. W. H. Brooke, J. W. Conchie, J. L. Cormack, F. L. Gooch, T. Slipper, F. B. O. Taylor, R. C. Trigger, S. M. Woodward, H. Yeomans, J. Young, and the Hon. Sec., Mr. H. J. Dawes.

Apologies for unavoidable absence were received from Messrs. E. Ringer, J. J. Burchinal, L. W. Heelis, R. L. Phillips, T. J. Brain, E. O'Neill, C. F. Parsons, J. R. Carless, J. Martin, W. Trigger, H. S. Reynolds, R. Hughes, and others.

#### THE DAWN OF PEACE.

The PRESIDENT said they could scarcely pass on to the business of the meeting without referring to the great change that had taken place since their last assembly. No one would then have predicted that we should have peace so soon, but fortunately the unexpected had happened and they met in better spirits in consequence. They of the Midland Association had tried to keep the ball rolling during the past four years, and, taking all things into consideration, he thought they had succeeded. He hoped at their next meeting they would be able to welcome back their absent members who had left their practices at their country's call and helped to bring about such a splendid result.

#### THE QUESTION OF FEES.

The minutes of the previous meeting were taken as read. The Hon. Sec. mentioned that the full report of the discussion on the proposed increase in the scale of professional charges was not published in the press, but a copy of it had been entered on the minutes. A copy of it had also been forwarded to the Royal College of Veterinary Surgeons and to the National Veterinary Association. He had received the following letter in reply:—

Dear Mr. Dawes,

I brought your letter and the accompanying copy of discussion at a recent meeting of the Midland Counties Veterinary Medical Association before the Parliamentary Committee at its meeting on Thursday last. The Committee passed a resolution of agreement with the opinion expressed by your Association, and this was formally adopted at a meeting of the Council held on Friday.—Yours faithfully,

FRED BULLOCK, Secretary.

*Nominations for Membership.* Mr. CORMACK nominated the following members of the profession for membership of the Association:—Mr. C. S. HUNTING, Loughborough, and Mr. JONES, Gloucester.

#### CONTAGIOUS ABORTION IN CATTLE.

J. L. CORMACK, M.R.C.V.S., Coventry.

Mr. CORMACK said: In choosing a subject for discussion to-day, I have been guided mainly in deciding upon Contagious Abortion in Cattle by the following factors: the very great prevalence of the disease; the enormous loss which it causes to agriculture and to the State; the rapid strides which have been made in recent years in a knowledge of it; and the necessity for further investigation of some of its aspects, so that we might be better able to deal with it.

It is a disease with which most of us come into contact almost daily, and upon which it is possible, even probable, that different individuals hold different opinions regarding some of its aspects. I trust that each member will to day express his opinion on the subject, and give his experiences of the disease in any connection, and more particularly if they are calculated to throw further light on our knowledge, especially in reference to getting rid of the disease or otherwise diminishing the losses caused by it.

Contagious abortion may be described as a specific catarrh of the uterus, caused by the bacillus of Bang, and commonly followed by the expulsion of the fetus. The expulsion may take place at any period of pregnancy, but most frequently from the fifth to the seventh month. Some recent writers suggest that this disease ought to be known by another name, such as "Bang's Disease," and one can quite understand that when he recognises than an animal may be infected with the disease without showing any evidence of abortion. I believe that such animals are capable of doing much harm in the way of spreading the disease.

Bang's bacillus is small, even smaller than the tubercle bacillus, non-motile, does not form spores, but is capable of living a non-parasitic life and retaining its virulence for months. It has been found to be capable of growth after as long as nine months. In a susceptible animal, it finds its most suitable place in the uterus, and especially in the pregnant uterus, which appears to be its seat of choice; but it is frequently found in the udder. It does not appear to remain long in the blood stream; but one would like to know whether this bacillus remains for any length of time in the alimentary tract, and if so, whether it can multiply in that position.

Infection is believed to occur most frequently by ingestion, through contamination of the food and water, and most particularly from grazing. In younger animals it is possible that infection is conveyed by the milk either through the presence of bacilli in the udder—which method is not regarded as serious—or through contamination of the teats by discharge which finds its way down the hind quarters of an infected animal and so become swallowed by a calf, or into the milk from the milkers' hands.

When infection takes place by way of the mouth, it appears to reach the uterus by way of the blood stream and so becomes deposited there, but as to how all this

comes about we have no definite knowledge. Several theories have been advanced as to possible modes of entrance into the uterus, but at present we must be content to accept the fact that the bacilli do, by some means or another, find their way into the uterine cavity. Infection *per vaginam* may occur during copulation or, as has been suggested, it may be possible that bacilli passed out in the faeces may be deposited on the vulva and find their way along the vagina and into the uterus.

With regard to the importance of the bull as a factor in carrying infection, there appears to be a difference of opinion, but the weight of evidence would show that while he is not so dangerous in this respect as was formerly believed, he is, nevertheless, capable of infecting cows. The bull can and does become infected with the abortion bacillus, but it is believed that in his system the bacilli do not find a suitable medium for growth, become attenuated, and soon disappear, so that one cannot attach much importance to the risk of infected semen. It is much more possible that the part played by the bull is purely mechanical, and that he is capable of infecting a cow only by serving a clean one within a comparatively short time of having served a recent aborter.

I may say Prof. Williams, of New York State College, has been investigating this subject, particularly in regard to the mode of entry of the bacillus into the uterus, and he, of course, accepts the belief that the chief infection takes place through ingestion, and that somehow or other the bacilli find their way into the blood and ultimately into the uterus. He points out that there are three great seats of the disease, or points of infection, in the uterus—the first and most important being the internal os uteri, and the apices of the two horns. I do not see that there is much to be gained from the practical point of view from that knowledge at the present time, but such knowledge may come in useful later on.

Symptoms of the disease are lacking unless and until some cow or heifer shows signs of slipping her calf, evidence of which may be seen a day or two, or only an hour or two before the act, and in cases occurring very early in pregnancy, the only signs may be the recurrence of oestrus after the animal is considered to have settled to the bull. In those cases which occur later, a discharge, frequently blood-stained at first, but later yellowish, may be noticed, accompanied by relaxation of the ligament, and to a greater or less degree, springing of the udder. It is from now that the animal becomes most dangerous, and begins to spread disease by dissemination of the highly infective discharge. In a large number of the later cases the placenta is retained, evidently as a result of the changes which are produced in the cotyledons by the catarrh. The cotyledons have a distinct yellow colour.

As to diagnosis, while one has usually some idea whether he is dealing with a case of contagious abortion, a definite diagnosis can only be established by the application of one of the following methods:—

(1) Microscopical examination of the exudate or discharge, which can best be procured from the fresh foetal membranes, and perhaps most readily from the cotyledons;

(2) The agglutination test. This is the most useful method and the one relied upon by most experts. It can be applied at any time, and is very delicate and reliable. This test may be applied with either of the following as the agglutinating media—exudate, milk (or better, whey), and blood serum. Blood serum is the most suitable, and is the medium almost invariably used.

(3) Complement fixation method. This is very delicate, and I believe very reliable, but is too complicated for general use.

(4) The abortion test; rarely, if ever applied now, and similar to the tuberculin test in its application.

Prevention is very difficult. It is almost impossible to keep a herd free from the disease in some districts—it is so prevalent and insidious. It will occur on farms which appear to be almost isolated, and to which there is seldom a fresh animal brought. In such cases the only explanation would appear to be that some agent acts as a carrier. It may be a man's boots, a dog, or other means of indirect contact. But much might be done in preventing the most serious source of spread by applying the agglutination test to all fresh cows before bringing them on to the premises. This could readily be done in the case of valuable herds, but it is not quite so practicable at present, where cattle are bought in the open market and while the disease is so common. It may be possible to do so one day, if we should be able to reduce the prevalence of the disease. Once the disease has appeared on a farm, the aborting animal should be immediately isolated and the most rigid sanitary measures adopted. Isolation of the cow should be maintained for several weeks, and certainly so long as there is any evidence of discharge. If remaining, remove the placenta, disinfect frequently the uterus and hind parts, including the tail and udder. Burn or bury deeply the calf and membranes. Thoroughly disinfect the premises, burn all litter, and disinfect utensils, men's boots, etc. Test all other members of the herd, and re-test them in six or more weeks, and should the case be an isolated one either have her removed to an infected farm or stall-feed her.

In badly infected farms, one would adopt vaccination in an endeavour to cut the outbreak short, and certainly to bring about a great saving both in milk and calf life.

It is pretty generally accepted that contagious abortion has a great tendency to wear itself out, and that many animals which have had an attack of the disease acquire a degree of immunity from it. Most animals acquire immunity after one attack, but many abort a second time, and some even a third time. To explain this may be difficult, but it seems feasible that many naturally infected animals will not have had a sufficiently large dose to provide complete immunity, and others may not be capable, for some unknown reason, of producing the immunising material in sufficient quantity. To hasten this immunity, the Board of Agriculture decided to experiment with animals by inoculating them with a large dose of bacilli. The experiments were successful; so also have been the extensive field experiments carried out in different counties, where the percentages of abortion have been reduced from sometimes as much as 70 per cent. to about 5 per cent., and even less.

The Hon. SEC., before the discussion continued, read to the meeting some notes on the subject recently issued by the Board of Agriculture for the benefit of breeders and veterinarians generally.

Mr. TRIGGER said the profession generally realised that this was one of the most difficult subjects they had to deal with at the present time. The loss which was sustained by stock owners was very serious, as it was to the public generally. The disease was allowed to run rampant through the country without any serious attempt to deal with it, until late years. It might be difficult, as the essayist said, to ascertain how the disease made its appearance at a certain farm, but he thought it was very wicked that a man, when he found that his cows began to abort, should at once send them to auction. He had heard farmers say they could pick these animals out before they aborted, and they soon got rid of them. These animals entered the market, their excretions were there, and farmers got it on their boots and so took the disease home to their own farms.

There should have been legislation on this subject years ago. Every man should be compelled to give notice of abortion on his farm, and cattle from that farm should not be allowed in any auction at all. The Board of Agriculture and the younger members of the veterinary profession were to be congratulated on what they had done so far, because he thought inoculation with vaccine had been attended with very good results. He was of opinion that vaccination should be compulsory on farms where abortion existed. He recognised that there was a difficulty, especially in a herd of 60 or 80 cattle, but they could be done in groups. There was no doubt that the animal that was doing most mischief was the one that showed no signs of disease. He thought it was rather a stretch of the imagination to say that infection took place while calves were sucking. Were they to believe that the bacilli remained in the calf until it was old enough to go to the bull?

Mr. GOOCH said he attended a meeting at Norwich two years ago, when Sir Stewart Stockman addressed the Norfolk Agricultural Association on this very subject. One of Sir Stewart's great points was that farmers should retain all aborted animals if they wished to get rid of the scourge. Farmers seemed to think it necessary to immediately get rid of an aborting animal from their herds, but Sir Stewart Stockman suggested that it would be better to keep them and breed from them again after using vaccine. He (Mr. Gooch) had had good results from retention and natural immunising.

Mr. TAYLOR said the subject was of great interest to the country practitioner. His own little experiments with the vaccine treatment had had good results. At one farm he vaccinated 24 heifers, according to the Board's regulations, and every one carried her calf. At another farm, three or four had slipped their calves, but they were vaccinated, and they now carried their calves right through. It would be interesting to know long this vaccine carried immunity. After vaccination, he had had some cattle fall off in condition, but he could not say whether it was a common occurrence.

Mr. YEOMANS said his experience of the subject was limited, but he thought that in future milk production was going to be such a very important branch of agriculture that there would be plenty of work for veterinary surgeons in the use of this vaccine test. If the results are satisfactory, which they promise to be, it would give them an opportunity of demonstrating to agriculturists the value of the veterinary profession, which would be a good asset to the general practitioner.

He would like to hear whether any member had had any experience of an outbreak of abortion in mares. Although dairy cows were very valuable, Shire mares were more so.

The HON. SEC. said he must first of all thank Mr. Cormack for his readiness in acceding to the request made to him for a paper. It was an example which he would like to see followed by other members. It seemed to him that this question of contagious abortion in cattle was much more difficult than it appeared to be. If a cow that has aborted has a calf put with it and is sent into the market it is a difficult thing to tell that it is an aborted animal. There may be nothing to guide you in the matter. Until something more definite was obtainable in a diagnostic sense, it was a disease that would take a lot of reckoning with. Again, a farmer was told that if his cow aborts he must take it into another building, but how many farms are there where that could be done? The farmer did not like turning a sick animal out of a warm shed. Another difficulty was that knowledge of the outbreak did not come to the veterinary surgeon first hand. The trouble had probably been going on for some time before the farmer mentioned it, and it had probably assumed extensive proportions before the veterinary surgeon

knew anything about it. Reverting to the question of the difficulty in telling aborted animals, he expressed the opinion that the State should take this matter up and submit all dairy animals to the test to find out whether they were affected. It would no doubt be a big undertaking, but it would help to get rid of the disease.

The PRESIDENT added his thanks to those of previous speakers for the very interesting discussion which Mr. Cormack had opened. Abortion in mares was a very serious matter, considering the value of a foal, but he did not think it was so widely spread and in such general epizootic form as in cattle. He understood that the casual organism was different in mares from what in cattle, and still different in the case of sheep. One point in the discussion seemed a little strange to him, and that was the effect upon calves. It was suggested that calves were infected with the abortion bacillus either through drinking milk from infected udders—not an uncommon seat of infection—or through sucking teats that have become infected by a discharge coming down the mother's hind quarters. He had some hesitation in accepting that, considering the length of time that must elapse before the calf became infected in that way and its having a calf of its own. If they could vaccinate cows that were non-pregnant with the abortion bacillus and two or three months afterwards safely put them to the bull, he could scarcely conceive that a cow infected years before would be likely to abort. The methods of infection were not altogether clear. As there was no direct opening in the womb through which the infective discharge might enter, they must look to the blood stream as the source of contagion. Mr. Cormack told them that the abortion bacillus was non-motile, so that it was difficult to understand how it entered the womb except through the blood stream.

With regard to prevention, where a farmer has no abortion, and he decides to keep his breeding at home, he will continue for a long period without a case on his premises. There was direct experience on that point in testing for tuberculosis; and by inducing a farmer to do his breeding at home, they had helped to stave off three of the most virulent diseases of the present day—Tuberculosis, Abortion, Johne's disease. He would like to impress upon every member the importance of persuading farmers to take every step that was possible in the eradication of those three diseases. If it was taken up properly, it was not an expensive matter to the farmer, and incidentally it was remunerative to the veterinary surgeon. With regard to the eagerness of the farmer to sell an animal that was likely to abort, he did not think the farmer really meant to do his neighbour an injury, but he only looked at the question from his own point of view. The only thing for the veterinary surgeon to do, and for the State to do, was to educate the farmer, who, if he knew he was going to financially injure his neighbour by selling him an aborting animal might be a little more careful. As to putting another calf to an animal that had aborted as a better means of selling it, that of course, was a very reprehensible practice. From what he could gather, both Sir John M'Fadyean and Sir Stewart Stockman were against compulsory legislation in the matter, but personally, he thought that any farmer who took a recently aborted cow out of his herd and sent her to the public market was guilty of an offence which ought to be punishable.

As to the retention of aborted animals, raised by Mr. Gooch, he thought everyone with practical experience would agree that it was the right thing to do. In ever so many herds, contagious abortion had gradually died out in the ordinary way. Unless any new cows were brought on to the farm, it generally died out in two or three years, so that when a cow had aborted it seemed

to be the right thing to keep it in the herd. Whether it was still capable of spreading abortion was another matter.

It would be interesting to know whether it was possible for infected milk to transmit the disease to the human being. He believed that some recent experiments had shown that it was not possible.

Mr. BROOKE said he would like to ask a question. As the alimentary tract seemed to be recognised as a frequent means of infection, he would like to know on what grounds that opinion was formed.

#### REPLY.

Mr. CORMACK said there seemed to be very few diseases in the country that were more important from a national point of view than contagious abortion in cattle. The loss spread over the British Isles in a year must amount to an enormous sum of money. Some years ago the loss estimated to occur from animals that aborted was £7-10-0 per head, so he did not know what the loss could be reckoned at to-day, with the price of cattle and milk so much higher than it was. As to sending an aborting cow to market with a normal calf, he should say it was a very shady practice which ought to be covered by some form of legislation.

Mr. TRIGGER: I should think it is a fraud, if you could prove it.

Mr. CORMACK said he thought Sir John M'Faydean and Sir Stewart Stockman were disinclined to suggest any form of legislation in regard to notification of the disease. Sir Stewart Stockman in one of his papers, said it would be too expensive for any particular district to take up. It would have to be administered all over the country from headquarters, and there would be very great difficulty in carrying out, which would probably amount to the paralysing of the cattle industry. With regard to the possibility of infection in the calf while sucking, he did not suggest that a heifer calf was going to carry the bacillus in her system until she was old enough to calve herself. But one could not get away from the possibility of the calf swallowing large numbers of bacilli from the milk and spreading them. He had not seen anywhere any remarks regarding the possibility of the spread of the disease by means of the faeces. Was it to be supposed, when infection took place by means of the mouth, that every single bacillus that got into the alimentary tract found its way into the blood stream, or must they conclude that large numbers of the bacilli were passed out in the faeces? The mouth was believed to be the main source of contagion, both experimentally and clinically, and practically all the evidence went to show that infection, certainly in the case of the uterus, was conveyed by the blood stream. If so, one must eliminate to a very great extent the question of infection by the vagina. When the disease was generally found in prescribed areas and in remote parts of the uterus, one must conclude that it arrived there by the blood supply. He did not see how they could get infection of the uterus through the vagina, unless it was through the agency of the bull. A great many heifers aborted at grass, so that the grass became highly infected and the disease was spread in that way. It is possible that an animal which has been vaccinated could spread infection by means of the bowels, and if she happened to abort she would certainly spread it by means of the discharge.

Mr. BROOKE: Vaccination would have no effect on the bowels?

Mr. CORMACK: I should think it might, because you can't get any part of the body that is not supplied with blood.

Mr. BROOKE: Except that the alimentary canal is outside the blood.

Mr. CORMACK, continuing, said that the retention of aborting animals was the only wise thing to do in cases

where the disease was present to any great extent. If there was only an isolated case, he advised testing the other animals, and re-testing in a few weeks time. If there were no reactors, he thought it would be foolish to retain that animal on the farm.

Mr. GOOCH: If natural immunisation takes place, why get rid of it?

Mr. CORMACK: Natural immunity does not always occur; you get disease a second, and even a third time. The results of vaccination have been exceptionally good, but he would not say that all the results were due to vaccination. He had not noticed any cases of loss of condition, referred to by one of the speakers, and he had not received any complaints about loss of milk through vaccination. He had no knowledge of the length of time infection might last in the alimentary canal.

He had seen some mares that slipped their foal, but he did not know that it was due to contagious abortion. It could be produced in a mare experimentally by means of Bang's bacillus, but the mare was not liable to contract this disease naturally. Abortion in sheep was also a distinct disease. There have been cases of cattle in which the causal agent was the vibrio which causes abortion in sheep, but such cases were rare. Abortion is not so prevalent in mares, and a point to note in this connection is that mares generally foal at one particular time of the year, whereas cattle calve at all times of the year, and as the pregnant uterus was the chief habitat of the bacillus it was kept vigorous all the year round. He thought the chief risk of infection through the vagina was that the bull might carry the infection from another cow, or he might inoculate the uterus with germs which he might take in from the lips of the vulva of the particular cow he was serving. He agreed that there was great need for the further education of the farmer in these matters as a means of checking the spread of the disease.

On the motion of the President, seconded by Mr. Gooch, a vote of thanks was accorded Mr. Cormack for his address, both gentlemen agreeing that the whole discussion had been very informative.

The company adjourned for tea before separating.

H. J. DAWES, F.R.C.V.S., Hon. Sec.

### COCCIDIOSIS IN THE RABBIT.

To the Editor of "The Veterinary Record."

Sir,—The last issue of *The Veterinary Record*, (4th January), contains a report of a meeting of the Central Veterinary Society, at which a paper on Coccidiosis in the Rabbit was read by Mr. J. B. Buxton, F.R.C.V.S., D.V.H. In the debate which followed apparently nearly every statement made in this paper was accepted as correct, or at least allowed to pass without challenge, and one member went so far as to say that "Mr. Buxton's paper would be of great value abroad as well as in England." I venture to say that that opinion is not likely to be shared by anyone who is well acquainted with the disease in question.

It appears to me to be much more likely that, if the erroneous statements made in the paper are allowed to pass uncontradicted, readers abroad may infer that the study of coccidiosis of the rabbit has been sadly neglected in this country, and it is the fear of that result which impels me to take upon myself a very uncongenial task.

Premising that "some knowledge of the manner of reproduction of the parasites is essential to the clinician in order that the spread of the disease may be satisfactorily limited," Mr. Buxton goes on to give a description of the life cycle of the parasite which is replete with errors:—

(1). Mr. Buxton says: "The oocysts are expelled from the body with the faeces, and under favourable con-

ditions of warmth and moisture the cell contents divide into two and then into four spherical bodies, called Sporoblasts."

This is an inaccurate account of sporoblast formation, and no one who has followed the process could have fallen into the error. I challenge Mr. Buxton to produce a preparation showing an oocyst containing two sporoblasts.

(2). Continuing the account of the oocysts, Mr. Buxton says: "If a rabbit ingests such a cyst, the wall becomes dissolved and the sporocysts are liberated. These in turn rupture and set free the sporozoites or falciform corpuscles."

Each of the sentences here quoted contains a misstatement. Since the publication of Metzner's observations it has been known that the wall of the oocyst does not become dissolved, that the sporocysts do not burst, and that the liberation of the sporozoites takes place without either of these things happening.

(3). Professing to describe the formation of microgametes, Mr. Buxton says: "The nuclei become elongated and comma-shaped, and two flagella appear towards the anterior extremity." He also gives a figure of a microgamete in support of this statement, but it bears only a most distant resemblance to the microgamete of the rabbit coccidium, and only serves to show that he had never seen the object he was describing.

What has just been said also applies to the figure which is labelled "Macrogamete" and shows an indentation marked "micropyle." Mr. Buxton evidently does not know that macrogametes do not possess a micropyle, the thing so named being seen only in the oocyst. But in point of fact the figure does not bear the most distant resemblance to either a macrogamete or an oocyst; and, if it is accurate, one can confidently assert that the object from which Mr. Buxton made the drawing was not a coccidium at any of its stages.

(4). With regard to the fertilisation of the macrogametes, Mr. Buxton states that "A single male element penetrates the female cell at the micropyle, which then closes."

This I believe to be a most unwarranted statement unless Mr. Buxton is prepared to vouch for the facts from his own observations, or to give the name of an authority who does.

(5). Mr. Buxton's description of the lesions is equally inaccurate. Abscesses are never formed in the liver in cases of coccidiosis in the rabbit, or, if they are, coccidia have nothing to do with their formation.

The bile ducts do not become more branched, and the connective tissue does not become hypertrophied, nor does it produce either venous congestion or atrophy.

Two courses are now open to Mr. Buxton. (1). He may vouch for the accuracy of the statements which I have criticised, but in that case he ought in justice to previous authors to have given his reasons for dissenting from them. (2). He may say that he was not professing to describe what he had himself observed, but merely quoting for the instruction of the Central Veterinary Society from the writings of others. Unfortunately he has made that line of defence very difficult, for the part of his paper which deals with the disease in the rabbit does not contain a single reference to any authority on the subject. The whole tenor of his paper conveyed the impression that he was giving the Society the benefit of his own observations, and, without demur, he accepted the compliments which appear to have been paid to him on that understanding.

It is also not open to Mr. Buxton to excuse himself on the ground that the errors which he committed were trivial or practically unimportant, for he told the "Clinicians" who he was addressing that a knowledge of the facts was essential "in order that the spread of the disease may be satisfactorily limited." He is therefore bound either to maintain the accuracy of his statements, or to

apologise to the members of the Central Veterinary Society for having misled them.—Your obedient servant,  
J. M'FADYEAN.

Ryl. Vety. Coll. 7th January.

#### THE R.C.V.M.A. AND THE COUNCIL R.C.V.S.

Dear Sir,—Isn't "Reform" a little illogical when he asked, in your last issue, for us to eliminate from our minds "those who study personalities prior to professional interests" after he himself indulged freely in them?

The bulk of the members of Council are representative practitioners and should know the requirements of the majority of the profession. If they being tame sheep, were to be replaced by others of improved capacity should we fare better? Why blame the few schoolmen for a greater number of the Council, who has the wisdom of the speechless parrot? It seems to me the few have more forcible characters than the majority.

I quite agree with Prof. Gaiger's remarks. The tame sheep representing the bulk of the profession are on the Council at the will of the majority of the profession. Please, fellow practitioners, don't talk, think, and grumble. Let us act. The ultra scientists have done more for the profession than the majority of practitioners, who have the wisdom of the ants. Judging by the latters' contribution to the sum total of veterinary knowledge and progress, it is with them "take all, and give nothing."

"ACTION NOT TALK."

Dear Sir,—I have read with considerable interest the "After War problems," reported in *The Veterinary Record* of 28th December last, and feel that our grateful thanks are due to the President of the Royal Counties V.M.A. for giving expression to the thought which has occupied many of our minds for some time past—that things were not altogether well with us.

There is no doubt that the profession is suffering from an anaemia of a very pernicious nature—an anaemia due in a great measure to the apathy of a goodly number of its members.

If steps are not immediately taken to infuse new blood into the ranks of our governing body the profession's parlous condition will become one of utter hopelessness.

The forthcoming election gives each one of us an opportunity to put our house in order. The veterinarians who have served their country well, and upheld the dignity of the veterinary profession in every sphere of military operations, will not, I opine, be prepared to return home to the old regime; and I appeal to them to support with their votes only those who will maintain the status we have gained during the war, and who will take reasonable interest in our destiny.

Many of the present Council have been vouchsafed long terms of service at the Council Board, and in the interests of the Royal College of Veterinary Surgeons, their retirement would now prove advantageous.

It is certainly time that we should free our governing body from the domination of those who, in the midst of weakness, have assumed autocratic rule, or whose only power is that conferred by virtue of official position.

Let us place on our Council men with broad views, sound judgement, and without the proverbial axe to grind—men who will use every endeavour to raise our profession to that position among the arts and sciences which its nobility and importance dictates.

I agree with Mr. Gaiger, that "long range sniping" does not make for good—one so often misses the mark, or hits the wrong one. To clear the trench which holds up our advance is strategically sound, and with this object in view, I subscribe myself,

BOMBER.

## TRIORCHIDY—CASTRATION.

"Scrutator," in your last issue, wrote:—"that the practitioner, against whom the case went, was speaking the truth—that he did remove two testicles."

I never said or did anything of the kind. What I did was to remove a testicle and a tumour in the spring of 1916, and remove a tumour in the spring of 1917, *i.e.*, only one testicle and two tumours. When the tumour dropped off some farm hands said it was a testicle, which I consider to be "bunkum."

It is not my opinion that it was a case of triorchidy.

"Scrutator" further writes: "It is a pity I did not proceed for a new trial, etc., so as to safeguard the profession against a further charge of unskillfulness—which it amounted to." "Scrutator" might have put it in another way—the profession ought to have proceeded to a higher court, to clear my reputation and safeguard the profession, etc. Many years ago, however, I put down the profession collectively as a dead letter.

"Scrutator" is also wrong as to "unskillfulness." The Judge found negligence in that I removed a healthy testicle, cut the scrotum open for removal of second testicle, that I found a healthy testicle and simply left it there.

If "Scrutator" had as much work in hand at the time of the trial as I had he would think twice before proceeding for a new trial. Personally, it would not be worth while as far as I was concerned. What I did was to put the country-side ablaze with copies of my letter as it appeared in *Record*: so much so, that at a subsequent Redhill Market I had quite an ovation—metaphorically speaking, carried shoulder high—and the defendant, and V.S. who supported him, were called unmentionable names.

In conclusion, had I realised so much before the trial as I did afterwards the case would not have come up at all. I would simply have written the defendant to stick my fee in a rather peculiar part of his anatomy, and added a rider to the effect that he was not to send for me again.—Yours, etc.

The Gables, Reigate.

CHAS. A. SQUAIR.

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

J. Abson, D.S.O., Maj. R.A.V.C.	£1	1	0

## ARMY VETERINARY SERVICE

## THE MILITARY CROSS.

The King has been pleased to approve of the following awards for distinguished service in connexion with military operations in France and Flanders. Dated Jan. 1, 1919:—

\* \* \* \* \*  
Capt. R. J. Vickers, Can. A.V.C., 2nd Can. M.V.S.

## ORDER OF THE BRITISH EMPIRE.

The King has been pleased to give orders for the following appointments to the Most Excellent Order of the British Empire, for valuable services rendered in connexion with military operations in various Fields (Dated Jan. 1, 1919):—

O.B.E. (Military Division).

*Italy*—Temp. Maj. T. Bone, M.C.; Temp. Capt. D. Starkey; Capt. (actg. Maj.) W. Stothert (T.F.).

C.B.E. (Military Division).

*Egypt*—Maj. (Temp. Col.) A. G. Todd, D.S.O.

O.B.E. (Military Division).

Capt. (actg. Maj.) V. A. Bartrum (T.F.); Capt. (actg. Lt.-Col.) W. J. Dale; Bt. Maj. G. E. Tillyard; Maj. (temp. Lt.-Col.) J. Kendall, Aust. A.V.C.

*Salonika*—Maj. W. L. Harrison, F.R.C.V.S. (T.F.); Temp. Capt. G. Moir.

## MOST HONOURABLE ORDER OF THE BATH.

The King has been pleased to give directions for the following promotions in, and appointments to, the Most Honourable Order of the Bath, for valuable services rendered in connexion with military operations in *Salonika* (dated January 1, 1919):—

C.B. (Military Division).

Col. (temp. Brig.-Gen.) Fitzpatrick Eassie, C.M.G., D.S.O.

## PROMOTIONS AND OTHER REWARDS.

War Office, Jan. 1.

The King has been pleased to approve of the following rewards for distinguished service in connexion with Military Operations in *Egypt* (dated Jan. 1, 1919):—

## THE MILITARY CROSS.

*Egypt*—Capt. G. C. Page, Aust. A.V.C., attd. 1st Sig. Sqdn., Aust. Engrs.

TO BE BREVET LIEUT.-COLONEL.

*Salonika*—Maj. (temp. Lt.-Col.) W. A. Jelbart.

TO BE BREVET MAJOR.

Capt. (actg. Maj.) C. A. Murray.

## HOME SERVICES.

The King has been pleased to give orders for the following promotions in, and appointments to, the Most Honourable Order of the Bath, for services in connexion with the War (dated Jan. 1, 1919):—

C.B. (Military Division).

Maj. and Bt. Lt.-Col. (actg. Lt.-Col.) Arthur Olver, C.M.G., F.R.C.V.S.

## ORDER OF ST. MICHAEL AND ST. GEORGE.

C.M.G.

Maj. and Bt. Lt.-Col. (actg. Col.) Wm. Samuel Anthony; Maj. and Bt. Lt.-Col. John James Aitkin, D.S.O.; Capt. and Bt. Maj. (actg. Lt.-Col.) Alfred Searle Head, F.R.C.V.S., R. of O.

## ORDER OF THE BRITISH EMPIRE.

The King has been pleased to give orders for the following promotions in, and appointments to, the Most Excellent Order of the British Empire, for valuable services rendered in connexion with the War:—

M.B.E. (Military Division).

Temp. Qrmr. and Capt. C. Budd; Hon. temp. Lieut. G. Hetherington; Temp. Qrmr. and Capt. R. Owen.

OFFICERS (Civil Division).

Lieut.-Col. Francis Dillon Hunt, Ahmednagar, Bombay.

## PROMOTIONS AND OTHER REWARDS.

The King has been pleased to approve of the following rewards for valuable services rendered in connexion with the War (dated Jan. 1, 1919):—

TO BE BREVET LIEUT.-COLONEL—Maj. G. C. O. Fowler, Ret. pay (R.A.V.C.).

TO BE BREVET MAJOR—Capt. A. F. Castle, F.R.C.V.S. (T.F.); Capt. (temp. Maj.) J. Tagg (T.F.).

TO BE MAJOR—Qrmr. and Capt. T. E. Campey, M.B.E.

The King has been pleased to give orders for the following appointments for valuable services rendered in connexion with Military Operations in *North Russia* (dated Jan. 1, 1919):—

O.B.E. (Military Division).

*North Russia*—Temp. Capt. (actg. Maj.) F. Chambers.

War Office, Jan. 6.

In a dispatch received by the Secretary of State for War from Gen. F. R., Earl of Cavan, K.P., K.C.B., M.V.O., Commander-in-Chief of the British Force in *Italy*, the following names of those officers whom he considered deserving of special mention were submitted:—

Capt. (actg. Maj.) T. J. Faithfull; Maj. (temp. Lt.-Col.) H. S. Mosley, D.S.O.; Capt. (actg. Maj.) W. Stothert (T.F.); Capt. (temp. Maj.) T. Bone, M.C.; Temp. Capt. D. Starkey.

Extracts from *London Gazette*.

WAR OFFICE, WHITEHALL, Jan. 3.

REGULAR FORCES. ROYAL ARMY VETERINARY CORPS. Maj. W. Jowett, S. Afr. Vety. Corps, to be temp. Maj. (Apl. 9, 1918, seny. Dec. 1, 1914) (substituted for notification in *Gazette* of Apl. 27 and May 30, 1918).

Jan. 4.

Maj. C. M. B. Harris, D.S.O., F.R.C.V.S., to be Lieut.-Col. (Dec. 15, 1915, but not to carry pay or allowances of that rank prior to July 1, 1917, unless holding temp. or actg. higher rank with pay and allowances).

Jan. 6.

The following temp. Capts. relinquish their commns. (Jan. 7), and retain rank of Capt.:—On account of ill-health—J. W. Bennett, T. A. Huband, W. Bugg; on account of ill-health contracted on active service—R. W. Glaister.

Jan. 7.

To be temp. Lts.:—H. L. Dixon (Oct. 18, 1918); J. S. Shepherdson (Oct. 24, 1918).

The following temp. Lts. relinquish their commns.:—H. L. Dixon (Dec. 5, 1918); J. S. Shepherdson (Dec. 7, 1918).

Jan. 8.

Temp. Lt. to be temp. Capt.:—G. C. Lawrence (Dec. 14, 1918).

## OBITUARY.

WM. CLATER WILKINSON, M.R.C.V.S., Hill Side House, Hemswell. Graduated, Lond: July, 1906.

### Successful Ballot at Belfast.

A sum of about £1,000 has been raised for the Royal Army Veterinary Corps Comforts Fund as a result of a ballot organised by Mr. J. Ewing Johnston, Veterinary Officer in charge of the Remount Department at Balmoral, Belfast; and Mr. F. W. Brittain. These gentlemen not only promoted the ballot, but carried out the whole of the arrangements, and the success achieved is a striking tribute to the energy and thoroughness with which they performed their praiseworthy work. There were 25 prizes, the first being a thoroughbred mare, the second a fat bullock, the third a sheep, the fourth a pig, and the fifth two tons of house coal. The draw took place in the Imperial Picture House on the afternoon of December 20th. The counterfoils of the tickets which had been sold were placed in a large churn, and the winning numbers were drawn by the Honourable Mrs. Herbert Dixon. Amongst those present were the Lord Mayor and Lady Mayoress (Sir James and Lady Johnston). A telegram was received from Colonel R. H. Holmes, C.M.G., D.D.V.S., Dublin, expressing regret for his unavoidable absence.

The Lord Mayor, speaking previous to the draw, said Mr. Johnston and Mr. Brittain had been indefatigable in bringing the claims of the Royal Army Veterinary Corps under the notice of the public, and they were entitled to the utmost praise for the efforts they had made to help the Comforts Fund. The officers and men of the Corps would realise that they had not been forgotten by the people of Belfast, and they would certainly appreciate the very handsome contribution which the promoters of the ballot were able to make to the fund for providing them with comforts during the festive season. (Applause.)

Mr. J. Ewing Johnston said the Royal Army Veterinary Corps Comforts Fund had supplied large quantities of warm clothing, stationery, books, magazines, pipes, tobacco, cigarettes, and brushes to units serving in France, Egypt, Salonica, Mesopotamia, Gallipoli, Italy, Russia, and Serbia. It had also provided two V.A.D. hospitals, working in connection with the veterinary and remount camps in France. Many of the senior officers had written to the honorary secretary testifying to the men's appreciation of the gifts. The subscriptions from Belfast had only amounted to about £400, but the contribution of £1,000 from the ballot was the largest donation the fund had received from any source. The

thanks of the promoters were due to the donors of the prizes, and especially to the members of the Dixon family, who were always in the forefront in any effort on behalf of war charities. Sir Thomas Dixon gave a handsome donation, the first prize was presented by Major Daniel Dixon, and through Captain Herbert Dixon they had been able to defray all the incidental expenses. (Applause.) Thanks was also due to those who had sold tickets, and to the directors of the Imperial Picture House for allowing them to hold their draw in their premises. (Applause.)

The draw was then made by Mrs. Dixon. It was decided that the first prize should go to the holder of the thirteenth ticket drawn, and the winner was Miss Thompson, Glastonbury Avenue, Belfast. The second prize went to Mr. E. Hetherington, Upper Newtownards Road, Belfast; and the third to Miss Macbeth, Carlisle Road, Londonderry.

On behalf of the promoters and a few friends, Miss Emilie Johnston, daughter of Mr. J. E. Johnston, presented Mrs. Dixon with a beautiful hunting refreshment case.

The Honourable Mrs. Dixon, in reply, said she regarded it as a great privilege to have been entrusted with the responsibility of drawing the winning tickets. The men to whom comforts were to be sent by means of this fund had devoted their efforts to the alleviation of the suffering of army horses. Those animals had experienced the horrors of the war just as much as the men engaged in it, and she hoped the people who had failed to win prizes would remember that fact. (Applause.)

The Lord Mayor said Mrs. Dixon had endeared herself to all of them by the work she had done during the war, and the same remark applied to every member of the Dixon family. They were ever ready to give their help in furthering any scheme for the benefit of our fighting men, and their generosity was unbounded. (Applause.)

On the motion of Mr. J. M. Hamill, seconded by Mr. J. A. Jordan, a vote of thanks was accorded the Lord Mayor for presiding, and the proceedings then terminated.—*The Belfast News-Letter*.

[Owing to pressure of other matter on our present limited space, the foregoing has unavoidably been held over.]

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1593

JANUARY 18, 1919.

VOL. XXXI.

## THE COUNCIL MEETING.

Perhaps the most noteworthy, and certainly the most pleasant incident at last week's Council meeting, was the presentation to the veteran Treasurer which commenced the proceedings. Such a compliment in the Council Chamber is a very exceptional event; but the services which evoked it are equally exceptional. Thirty-four years of hard and continuous Council work have placed us under a debt which can never be repaid; but this little offering was a graceful recognition of it. The President, in making the presentation, expressed himself very happily; and his words will be endorsed by the whole profession.

The financial report was rather worse than usual, mainly from the few students presenting themselves at the Christmas examinations, partly from the inevitable falling off of voluntary subscribing at the end of the year. We all know the one way of retrieving the position before the April meeting.

All members will wish well to the Mettam petition, and some may be able to help it forward. The President especially asked Councilmen in a position to obtain influential signatures to do so; and not a few outside members may find themselves able to do the same thing. Those who can should lose no time in communicating with the Secretary.

Some other subjects dealt with were important, but none seem to require much comment at present. Some were briskly discussed; but in almost, if not quite every instance the discussion was more or less superfluous. Still, those who read the report carefully will discover some points of interest. Veterinary demobilisation is impossible at present; but the progress already made with the schemes for the re-settlement of veterinary surgeons in civil life and for financially assisting would-be veterinary students augurs well for the future prospects of the profession. Our Bill is to be re-introduced in Parliament, and an attempt is to be made to get it adopted as a Government measure; and we all understand how much depends upon whether that can be accomplished. A little correspondence item regarding the supply of linseed oil will be cheerful reading to many practitioners, especially to the country men. Lastly, it is pleasant to congratulate President and Council on having, at the first meeting after the cessation of hostilities, secured an attendance large enough to act upon Registration Committee reports. It was not done easily, but it was accomplished; and we may hope that it marks the end of the most serious cause of complaint that the profession has had against the Council's work during the war.

## ACTINOMYCOSIS IN A MARE, TREATED WITH AUTO-VACCINO-THERAPY.—RECOVERY.

By WM. SCOTT, F.R.C.V.S. F.R.M.S., Bridgwater.

*Subject.* A six-year-year-old light draught cart mare.

*History.* On the 15th Feb., of this year, I was asked to prescribe for this patient, the owner complaining of her being "tight in her coat." A course of Arsenic, Ferri sulph. and Sodii chlor. was supplied. The mare becoming worse and losing in condition, I was asked to see her on the 10th April.

*Symptoms.* The patient walked very stiffly, dragging her hind legs, which were kept widely apart; when turned, the whole trunk appeared rigid, giving the animal the appearance of suffering from tetanus. The left mamma was considerably swollen, hard, and fibrous to the touch, except at a point close to the base of the teat, which was fluctuating, suggesting the pointing of an abscess. The right mamma appeared perfectly normal. The functions of the panniculus carnosus were entirely obliterated, the skin was fixed and rigid, save in those areas covering the upper two thirds of the neck, on the head, on the inter-maxillary space, on the lower and lateral areas of the abdomen save that of 12 or 15 inches in front of the mamma. Over the regions of the back, loins and chest the skin was absolutely fixed, in fact the animal felt as if she might have been subcutaneously encased in a thick sheet of lead. Over the fore-arm and scapula, under the line of the trachea, and extending about 18 inches in front of the mamma along the abdomen, could be felt distinct cords with equi-distant nodules. If the hair was wetted with oil or water these areas could be seen to stand out prominently. There were no indications of suppuration or ulceration in these parts. It is reasonable, however, to anticipate that such developments would have taken place had the case been allowed to run its course. In any case a "cold" abscess had formed in the udder.

*Clinical diagnosis.* A malignant neoplasm having its origin probably in the udder, from which extension had taken place through the lymphatic network to the subcutaneous structures.

My previous experience of a parallel case occurred in the year 1910, which was treated on general lines with negative results and the animal had to be destroyed. No post-mortem examination was made and I did not suspect actinomycosis, nor did I in the case under discussion up to this point.

*Bacteriological diagnosis.* (a) Microscopical.—The skin of the mamma covering the pointing abscess was scrubbed with lysol, dried with cotton-

wool, painted with iodised petrol, and lanced with a sterile lancet. About 50 c.c. of pus was evacuated, the last few drops being collected in a sterile tube (marked No. 1) and plugged. A further collection was made by inserting a sterile curette and lightly scraping the abscess cavity wall. This was placed in another sterile tube (No. 2).

The pus was very viscid and glairy. A drop from No. 1 tube was placed on a clean slide, and another slide applied to it and pressed firmly, they were then parted, the smears fixed and stained by Gram's method and examined under the microscope. Save for the usual pus elements, minus bacteria, nothing positive was noted. A drop of pus from tube No. 2, similarly treated, revealed in addition several star-shaped colonies, the central portion consisting of principally a mass of cells densely packed, and radiating from this mass a network of entangled threads on the outer zone of which a few well-defined club-shaped elements were noted. These were flask-shaped, the neck portion being joined to the thread. Several giant cells were also seen in this field.

(b) Biological.—Nutrient agar (plain), Litmus agar, glycerine agar, and blood agar tubes were inoculated from the pus contained in tube No. 2, and incubated at 37° C. On the seventh day of incubation in the glycerine tube, small, pale, almost transparent, bead-like colonies were noted. Three days later fully developed rich, white porcelain-looking colonies with slightly crenated edges had formed, giving the whole surface of the tube the appearance of a network of fine roses, such as is seen in old Valenciennes lace. These colonies had roots firmly embedded in the media, and if the surface was removed by a platinum loop, or even scraped with a fine sterile lancet fresh growths would rapidly recur; the cultures were pure throughout, and subsequent sub-cultures grew rapidly and easily on plain agar in 24 to 30 hours. From these I obtained my vaccines. With a sterile loop a removable portion of a colony was picked up, mixed with a drop of distilled water previously placed on a grease-free slide, dried and stained: the following elements were noted. Somewhat dense tufts of mycelia, usually irregularly arranged, some, however, showed a faint semblance to radiation, many of the threads were branched, and a few at their distal ends carried clubs. The threads took the aniline stains well. Numerous cocci-like elements were also seen in the field.

*Treatment.* (a) General.—The animal was running at grass, and was allowed to do so with the exception that she was brought indoors at night till late in the spring. The abscess cavity in the udder was irrigated three times with a solution of proflavine and sodium cit., and the following prescribed:—

R. Sodii citratis  
Sodii chloridi aa ʒj.  
M. Ft. pulv. mitte xii.  
Sig. Pulv. Bis in d.

(b) Special.—As soon as I was able to isolate what appeared to be the specific organism I decided to test the efficacy of vaccination, for which

purpose this case, to my mind, lends itself most admirably, for here we had a distinct and visible set of progressive pathological phenomena in evidence. As this was the first case of equine actinomycosis which I had treated by vaccination the degree of dosage was largely experimental, and I had to fall back on my observations made in the treatment of nine cases in cattle of lingual, parotideal, sublingual, buccal actinomycosis. In nearly all those cases the dose was standardised by weight. In this case I decided upon a numerical count. The cultures were scraped off the surface of the media with a small spoon-shaped curette, a small portion of the medium being removed in the process. This was allowed to macerate for a few hours in distilled water, being shaken at intervals. Ten or a dozen beads were then added and vigorous shaking applied, the object being to break down the mycelia in short segments, to permit counting in the usual way, *i.e.*, against the corpuscles obtained from one's own blood. The following standard of doses was then administered every seven or nine days:—

Day.	Dosage (millions).	Local reaction.
1st	750 sterile	Small swelling disappears in 4 or 5 days.
2nd	1000 sterile	
3rd	1000 (v) attenuated	Slight swelling.
4th	2000 (s) attenuated	Same.
5th	3000 attenuated	Same, somewhat painful.
6th	500 virulent	*Considerable swell'g. hot, painful; abscess form'd
7th	750 "	*Same.
8th	1000 "	Swelling, no abscess.
9th	1500 "	Same.
10th	1750 "	Same.
11th	2000 "	Very slight swelling, no abscess.
12th	2500 "	Same.

\* In the pus from abscesses developed after injections a few Mycelia were detected under the microscope, but I was unable to obtain cultures therefrom.

On the second day after the sixth injection, in addition to the local, there was considerable general reaction. The animal was off feed, moved somewhat stiffly, and the temperature was raised two degrees. This negative phase lasted about 36 hours. After the seventh and subsequent injections no further reactive general phenomena were noticed.

*Observations.* At the outset the tenseness of the skin limited one's opportunities of inserting the hypodermic needle to those areas in which the disease had not spread and which have been previously mentioned. A fine hypodermic needle could be inserted into the diseased subcutis with much difficulty, but it was physically impossible to infiltrate even 1 c.c. of fluid, showing how intimately bound up the cutaneous and subcutaneous elements were. After the third injection the stiffness was considerably less, and the animal even attempted to trot. After the fifth injection the skin covering the ribs, shoulders, and the loins was beginning to relax, and one could discern in places slight panniculus carnosus twitchings. The hypodermic needle could now be inserted wherever one chose; the most extensively diseased areas were, from this date, selected as the seats for inoculation, and I was much struck with the fact that radiating from these inoculation centres, the diseased areas pro-

gressively disappeared, clearly proving the specific local reactive power of the antigen used. It is also interesting to note the powerful influence exerted by the virulent antigen over the almost non-virulent one when the quantum used was six of the latter to one of the former—even in a patient where by reason of the previous injections a certain degree of hyper-immunity had been reached.

I may here add that our patients, especially the larger ones, lend themselves admirably to immunisation by *active* antigens as against *sterile* antigens in many chronic diseased conditions, with few exceptions. The reason being, the reproductive processes going on in the active antigenetic elements phagocytosis becomes more forceful and prolonged.

The patient was seen by me a few days ago, she had been put to work, and the only trace of the disease was to be found in a slight corded swelling extending under a third of the trachea, and a similar swelling about four inches long immediately under the skin at the posterior border of the infra-spinatus muscle on the left side. In every other area the infiltrate had completely disappeared; the subcutis had regained its normal consistence, the skin its elasticity, and locomotion became normal.

The excellent responses obtained by auto-vaccination in this case gives encouragement for future effort along those lines, particularly in those obstinate cases where the iodine treatment has failed to give results. There are several records in human pathology of the application of vaccine therapy, but in comparative pathology it appears to have been entirely ignored. I record this case as an incentive to others to adopt its tenets and publish their results, thereby adding to our fund of knowledge in their treatment of this important disease.

\*\* I look upon those two swellings as post-fibrous deposits rather than centres of future infection, for they appear to be isolated and encased.

## Royal College of Veterinary Surgeons.

### QUARTERLY MEETING OF COUNCIL.

A Quarterly meeting of Council was held at 10 Red Lion Square, London, W.C., on Friday, 10th January.

Mr. FRANK W. GARNETT, C.B.E., J.P., President, occupied the chair, and the following were present:—Maj. J. Abson, D.S.O.; Messrs G. A. Banham, W. F. Barrett; Maj.-Gen. L. J. Blenkinsop, D.S.O.; Dr. O. C. Bradley; Lt.-Col. J. W. Brittlebank, C.M.G.; Messrs. J. H. Carter, J. C. Coleman; Prof. S. H. Gaiger; Mr. A. Lawson; Sir John M'Fadyean; Messrs. J. McKinnon, W. J. Mulvey, W. Packman, T. S. Price; Prof. J. Share-Jones; Mr. S. H. Slocock; Sir Stewart Stockman; Messrs. H. Sumner, R. C. Trigger, S. Wharam; Mr. Geo. Thatcher, Solicitor; Mr. Fred Bullock, Secretary.

*Minutes.* The minutes of the last meeting, which had been printed and circulated, were taken as read, and confirmed.

#### PRESENTATION TO MR. W. J. MULVEY.

The PRESIDENT: Gentlemen, before proceeding to the ordinary business of the Council I have a proposition to put before you, namely, that we record on our minutes

the services of one of our members—Mr. W. J. Mulvey. (Hear, hear). He has been a member of this College for a longer consecutive period than anyone in the history of the College. He was first elected in 1885, and there are very many memorable landmarks connected with his long period of office. The very year in which he was elected saw the building of our present establishment, which in itself was one of the first landmarks in our history. Then he was one of those who took a very prominent part in regard to the Charter of 1878. He was elected President in the year 1892-3, which is also another very important landmark in the history of the College, because in that year we established the four years course instead of the three years course. I have not gone through all the records, but I have not the slightest doubt that Mr. Mulvey was one of the pioneers of that, because he had been a member of the Examination Committee since 1887. He has been the Chairman of the Examination Committee with, I believe, but one single break since 1894; He has been a member of the Finance Committee since 1887, and on the death of Mr. Wragg he was unanimously elected Treasurer, a position which he still holds, and holds, as you know, to the entire satisfaction of the whole profession. (Cheers). No words of mine can convey to Mr. Mulvey the value the Council and the profession attach to his services. Every one of the letters that have been received from the members of the Council in regard to this token of appreciation to him, contain words as to the value of his services, not only to the Council, but to the profession throughout the country; and I feel sure that I am voicing, not only the opinion of the Council but of the profession generally, when I say that it is recognised by all that no one has rendered greater service to us than Mr. Mulvey. (Cheers). On your behalf I ask him to accept this small token of appreciation, and to express the hope that he may be spared to give us his valuable services and wise counsels for many years to come. (Cheers).

The President then presented to Mr. Mulvey the very handsome solid silver tea service, in the Queen Anne period, consisting of a tray, a teapot, sugar basin, and cream jug, all of which bore Mr. Mulvey's monogram, while the tray bore the following inscription:—

"Presented to W. J. MULVEY, J.P., F.R.C.V.S., by members of the Council of the Royal College of Veterinary Surgeons in appreciation of his services to the Council and profession during the period of 34 years. January 10th, 1919."

Mr. MULVEY, who was very heartily cheered on rising to respond, and who spoke under considerable emotion, said:—

Mr. President and Gentlemen,—It is very difficult for me to reply to the exceedingly eloquent words that you have used in regard to the small services that I may have been able to render to this Council and to the profession. Believe me that I appreciate them very highly. As you say, sir, I have been a member of the Council for a considerable number of years, and it has occurred to me from time to time that I ought, as has been suggested, to retire and make room for a younger man. (Loud cries of "No, no"). But I feel young yet. (Cheers). It is not always a question of how long a man has lived, if he keeps his heart young and he feels that he is able and willing to carry out the duties that he has not only taken upon himself but which have been imposed upon him. (Cheers). With me this work has always been a labour of love. From my earliest days in the profession I have loved it, and I have done all in my power to promote its best interests. (Cheers). Looking round this room I regret to say there is not a single member left with us who was here when I first entered it. When I first joined the Council our meetings were held at a house across the road, while these premises

were being rebuilt. I was here in this room at the first meeting held in it, Mr. John Roalfe Cox then being President, and that meeting was followed by a lunch in this room. That is a few years ago. From time to time, by the good will of the profession, I have been elected, and I am still here. (Hear, hear). Really, I think I have still a little more work left in me, and until I am turned out I am going to stay. (Laughter and cheers). For this very handsome present I return you my sincere and hearty thanks. Believe me, I appreciate it, and shall do in the future. (Cheers).

*Apologies for absence.* The SECRETARY announced that apologies, regretting their inability to attend the meeting, had been received from Mr. Clarkson, Mr. John Dunstan, Maj. Gofton, Mr. P. J. Howard, and Maj. John Thomson.

*Obituary.* The Secretary read the obituary list.

*Admissions to membership.* The Secretary announced that since the previous quarterly meeting the following had been admitted to membership:—

*London—*

Mr. H. W. Brekke  
I. R. R. Coleman  
L. N. Devenish  
C. P. King  
H. Thornton

*Liverpool—*

Mr. H. Salusbury  
A. Williams

*Glasgow—*

Mr. C. Macpherson

*Dublin—*

Mr. M. A. O'Connor  
J. J. O'Donovan  
M. G. West  
W. White

*Correspondence.* The SECRETARY announced that the only correspondence received was a card containing best wishes from Frederick Hobday, No. 22 Veterinary Hospital, B.E.F., Italy, Christmas, 1918.

#### FINANCE COMMITTEE.

Mr. LAWSON read the report of a meeting held on January 10th:—

The Treasurer submitted his financial statement for the quarter, showing a balance in hand of £392 15s. 4d. and liabilities amounting to £592 18s. 9d.

It was resolved: That the Treasurer's statement be approved, and that he be ordered to pay cheques for monthly salaries, petty cash, electric light, Fidelity Insurance, and subscriptions for foreign journals, required during the ensuing quarter.

The President reported that during the Secretary's illness a large amount of extra work had been imposed upon Miss Blake.

It was resolved: That a bonus of £5 be paid to Miss Blake, and that she be thanked for her extra services.

An application was received from Mr. W. A. Benham, who had been in the army since May, 1917, for re-engagement on demobilisation.

It was resolved to recommend: That Mr. Benham be informed that the Committee is prepared to re-engage him at a salary £120 per annum.

Mr. TRIGGER: I move the adoption of the report.

Mr. PRICE: I second that.

The PRESIDENT: Probably the Treasurer has something to say on the report of the Finance Committee.

Mr. MULVEY: I am afraid, sir, it is only the old tale, that the balance is on the wrong side. If it had not been for the fact that we were able to draw £200 from the deposit account I do not know how we should have got on. As you will notice, our deficit is very large this time. The number of students has been so small, and the expenses do not get any less. The only thing I can do is to entreat the members of the profession to keep up their subscriptions, and to ask those who have not already subscribed to make up their minds to do so. (Hear, hear).

The resolution of the adoption of the report was then carried unanimously.

#### REGISTRATION COMMITTEE.

The SECRETARY read the minutes of a meeting held on 9th January, from which it appeared that 15 cases were considered by the Committee. In the case of J. Akehurst, non-member, the Solicitor reported that a conviction had been obtained, and a fine of £5 and costs imposed.

Two cases were ordered to be struck out; it was resolved in one instance that there was no case; it was resolved in two cases that prosecutions should be instituted, and also in another case, subject to the Solicitor obtaining satisfactory evidence; in another case he was instructed to send a notice of warning; two cases were ordered to stand over for further enquiry; and the Solicitor reported that the prosecution instituted against H. Smith, non-member, had been dismissed. One other case was withdrawn by the complainant.

A member was charged with drunkenness on active service, and conduct to the prejudice of good order and military discipline when in His Majesty's service, and was convicted thereof at a General Court-Martial and cashiered. He appeared before the Committee, accompanied by his legal advisers. The College Solicitor put in a certified precis of the charge and conviction before the Court-Martial, and also read the evidence before the Court-Martial as contained in a certified copy of the proceedings, in which Capt. Crosbie said he had known this member for a number of years; that he had a high reputation as a veterinary surgeon, and that he had never known him to be drunk nor heard of his being drunk before the occasion in question. The sentence that he be cashiered was confirmed by Field Marshal Haig. The member gave evidence before the Committee and denied drunkenness. Dr. Blair said that the man was in bad health, suffering from palpitation. He tried to get him to go to hospital or a rest camp without success. Mr. O'Malley, Counsel, addressed the Committee on behalf of the member.

It was resolved: That the Committee find the charges proved.

*Application for Restoration.* An application was received from Mr. A. E. Webber for the restoration of his name to the Register, it having been removed by the Registrar under Section 5 Sub-section 4 of the Act. It was resolved: That the Registrar be authorised to restore the name of Mr. A. E. Webber to the Register of Veterinary Surgeons.

Mr. TRIGGER: I move the reception and adoption of the report.

Mr. MCKINNA: I second that.

Mr. LAWSON moved, Mr. PACKMAN seconded, and it was resolved: That the Seal of the College be attached to the prosecutions recommended in the report.

The PRESIDENT: There is not a quorum of members present yet, so that we must defer till a later period of the meeting the question of whether or not the names of the two members shall be erased from the Register.

#### PARLIAMENTARY AND GENERAL PURPOSES COMMITTEE.

Dr. BRADLEY read the report of a meeting held on January 9th, 1919, and moved its reception and adoption:—

*Mettam Appeal.* The sub-committee appointed to consider this matter met on December 6th, when the solicitor submitted a draft of a petition to the First Commissioner of His Majesty's Treasury, praying for the grant of a Civil List Pension to the widow of the late Professor Mettam. The draft petition was settled as amended, and the Solicitor was instructed to have prints prepared in time for the next meeting of Council.

The Solicitor submitted prints of the appeal, which had been circulated.

It was resolved to recommend the following resolution be included in the Petition.

"That in the opinion of this Council the late Professor Mettam, by the arduous devotion of his life to teaching and research in connection with Veterinary Science, rendered great service to the nation, and especially to the interests of agriculture; that owing to his death at a comparatively early age, and the inadequacy of the salary attached to the appointments which he held, his widow and family have been left in straitened circumstances; and that the Council should therefore support by every means in their power a petition to H.M. Treasury for a pension to be granted to Mrs. Mettam."

Lt. Col. BRITTLEBANK seconded the motion.

The PRESIDENT: With regard to the petition for a civil pension for Mrs. Mettam, I hope every member of Council will take as many copies as he can and get them signed by as large a number of influential people as possible in their respective districts, particularly people who have influence in Government quarters—Lord Derby, for instance, if somebody could put his signature, and the heads of Universities, and members of Parliament who are in touch with the Prime Minister. These will have a very great effect, and it is hoped that the petition which is being lodged and is being repeated by the Irish Department of Agriculture will, with this backing, be successful. We want to make the backing as strong as possible.

The motion for the adoption of the Report was then put, and carried unanimously.

*Production and Distribution of Milk.* The Secretary submitted a copy of the Third Interim Report of the Committee on the Production and Distribution of Milk, together with forms issued by the Local Government Board giving conditions for licenses for the purchase and sale of milk of special quality.

It was resolved to recommend that a Special sub-Committee be appointed, consisting of Dr. Bradley, Lt. Col. Brittlebank, Sir J. McFadyean, Mr. T. S. Price, and Mr. S. H. Slocock, to consider this question and to report to the next meeting.

*Linseed Oil.* A letter was received from the Linseed Oil Consumers Association, stating that it was not now necessary to proceed with the scheme for the distribution of Linseed Oil reported at the previous meeting of the Committee.

#### EXAMINATION COMMITTEE.

Mr. MULVEY read the reports of meetings held on 12th December, 1918, and 9th January, 1919:—

*Assistance to Veterinary Students.* The following letter was received from the Board of Agriculture:—

L5562/1918. 9th December, 1918.

Sir,—With reference to your letter of the 3rd December, I am directed by the President of the Board of Agriculture and Fisheries to enquire whether the Council of the Royal College of Veterinary Surgeons can estimate what proportion of the sum of £7,500 suggested for scholarships for students whose studies have been interrupted, would be required for scholarships to be held by such students at Colleges in England.

2 I am further to enquire whether the College can form any estimate of the number of discharged officers and men who would wish to enter the veterinary profession, but whose means are insufficient to enable to undertake the course required for qualification; and of the number of such students for whom accommodation and instruction can be provided at the existing veterinary colleges in England during the next four years. Mr. Prothero presumes that in the view of the College the demand for qualified practitioners in the veterinary profession is likely to be such that at the end of their course of training discharged officers and

men would find no difficulty in making a reasonable livelihood.—I am, Sir, your obedient Servant,

H. E. DALE.

It was resolved that a reply be sent to the following effect:—

(1.) The total number of students whose studies have been interrupted by military service is 178 of whom 82 were studying in England, 72 in Scotland, 24 in Ireland. It is recommended that the sum of £7,500 be allotted to the three countries in a proportion corresponding with these figures.

(2.) The committee is unable to estimate with any pretence to accuracy what number of discharged officers and men may wish to enter the profession, but the information of the committee is to the effect that a considerable number of applications have recently been addressed to the different veterinary schools by officers and men requesting information as to the conditions under which they can qualify as Veterinary Surgeons.

The number of such students for whom accommodation and instruction can be provided would depend upon the number of new students other than discharged officers and men. It is calculated however that accommodation could be found at the four Colleges in Great Britain for at least 100 discharged officers and men per annum during the next four years, in addition to the number of students included in paragraph 1.

So far as the Committee is able to estimate the prospects of veterinary graduates in the near future, it has no hesitation in saying the prospects are likely to be excellent. There is no doubt whatever that they will without difficulty be able to make a good livelihood.

*Resumption of Studies by Demobilised Students.* A letter 5 12/1918 from the Ministry of Labour, Appointments Department, was communicated by Prof. Gaiger, in which the question was raised as to the possibility of making arrangements whereby demobilised students should lose the minimum of time in resuming their studies.

It was resolved that the matter be deferred pending the receipt of a direct communication on the matter from the Ministry addressed to the Council.

#### APPLICATIONS FOR EXEMPTION FROM PRELIMINARY EXAMINATIONS.

J. R. POPE. A Lieutenant in the army who enlisted at 16 years of age, recently invalided after three years service. A recommendation from the Head Master of St. Paul's School was submitted.

It was resolved that Lieut. J. R. Pope be exempted from the Preliminary Educational Examination.

J. JACKSON, O.T.C. An application for exemption from completing his preliminary educational certificate.

It was resolved that the application be not acceded to.

G. A. BELL. Application, accompanied by testimonials from the Head Master of Boroughmuir School, Edinburgh, and the Rev. R. G. Strang, of the Edinburgh School.

It was resolved that Lieut. G. A. Bell's certificate be accepted as qualifying him in respect of general education to enter a veterinary college.

W. MAITLAND. Private in the army since 1914, accompanied by certificate.

It was resolved that the application be not acceded to.

N. DOBSON. Sergeant R.A.M.C. Application accompanied by testimonials.

It was resolved that Mr. Dobson be exempted from the Preliminary Educational Examination.

P. J. NEENAN. Bailiff to the Besford Court Farm Colony.

It was resolved that as the applicant has not served in one of H.M. Forces, application cannot be acceded to.

D. TELFER. Discharged soldier. Application to be allowed to take his preliminary educational examination

at any time before taking the first professional examination.

It was resolved that the application be acceded to.

Applications from the following were deferred for further information:—

C. B. F. Parkinson. J. A. Craft. H. F. Hoffmann.

#### EXEMPTIONS FROM THE FIRST PROFESSIONAL EXAMINATION.

**T. J. RICHARDSON.** Rejected in Anatomy only at Class A Examination, July 1917. Served with forces since that date.

It was resolved that Mr. T. J. Richardson be allowed to proceed to the second years course on the understanding that he will be required to take whole subject of anatomy at the Class B examination.

**T. W. M. CAMERON,** Capt. R.A.F. In army since August 1914. Application for exemption from Class A examination. Second year Medical and Science Student. Certificates in Chemistry, Nat. Philosophy, Zoology, Mathematics.

It was resolved that Mr. Cameron be informed that, under existing Bye laws his request cannot be acceded to; but an alteration of Bye law is contemplated which would render him eligible for exemption from the Class A examination.

**C. MACAULAY,** Sergeant. M. A. Glasgow. First year B. Sc. Course. No examinations taken.

It was resolved that Mr. Macaulay be exempted from the first professional examination provided he passes the qualifying examinations in the subjects required by Byelaw 62a.

*Demobilisation of Veterinary Surgeons.* A letter 5/12/1918 was received from the Board of Agriculture asking to be informed of the steps taken by the College to secure the demobilisation of Veterinary Surgeons at an early date.

It was resolved to recommend that a special Sub-Committee consisting of the Chairman of the Examination Committee and the President be appointed to deal with applications for priority of demobilisation of Veterinary Surgeons.

The following resolution was received from the Royal Counties V.M.A.:—

"That the Royal Counties Veterinary Medical Association agree that a resolution should be forwarded to the Royal College of Veterinary Surgeons urging upon them the advisability of keeping a Register of practices for sale, assistants wanting occupations and also vacancies for assistants whereby those members returning to civil life from the army may have the opportunity of being placed in suitable employment, and that a small charge be made to cover expenses."

It was resolved that the Secretary be authorised to announce in the Veterinary Press that during the period of demobilisation he will be willing to receive information from—Members of the profession who require qualified assistants. Members who desire appointments as assistants. Members who wish to dispose of, or to purchase a practice. Members requiring partners, and those seeking partnership.

9th January, 1919.

*Reports on December Examinations.* The SECRETARY submitted reports from the Chairmen of the Board of Examiners and local Secretaries on the December examinations.

The Secretary reported that the following special appointments of Examiners had been made:—

*Class A.—Biology.* Capt. B. Butler was appointed Examiner in Zoology in Dublin, and Mr. R. W. H. Row, B.Sc., in London, in place of Mr. Ainsworth Davis.

*Class B.—Histology.* Dr. P. Lamb was appointed in place of Sir W. Henry Thompson.

*Class C.—Pathology.* Dr. Bulloch was appointed in London, in place of Dr. McWeeney, who was unable to travel to London.

*Class D.—Surgery.* Mr. J. Malcolm was appointed to examine in place Major W. S. Mulvey, unable to act on account of illness.

It was resolved: That the appointments be approved. That the usual letter of thanks be addressed to those persons and institutions who have assisted in the conduct of the examinations.

Educational Certificates numbered 1722 to 1732 were submitted and approved.

Applications for exemption from Preliminary Educational Examination were received from the following ex-service officers and men, in each case accompanied by school certificates:—

1733. BRETHERTON, R., Lt. R.G.A.

1734. PEIRSON, W., Private R.A.M.C.

1735. CRAFT, J. A., Flight Cadet, qualified for Commission.

1737. LANGFORD, E. G., Sergt. R.A.V.C.

1738. McEWEN, A. D., Lt. R.F.A.

1739. PARKINSON, C. B. E., Lt. R.F.A.

1740. WELSH, W. C., Lt. R.F.A.

1743. WALPOLE, B.O.E., Lt. R.F.A. (subject to the production of a school certificate to be approved by the Secretary).

1744. ARMSTRONG, H. J., (Certificate approved *pro tanto*, 8th April, 1918).

1745. HUMPHRIES, H. D., Lt. R.A.F.

1746. WESTON, —, Coll. of Preceptors Certificates.

It was resolved: That the applications be acceded to.

*Exemption from part of A examination.* Applications were received from Lt. D. Coady and Lt. T. Treacy for exemption from the first professional examination in addition to the preliminary educational examination. Certificates were submitted as to examinations passed in Chemistry and Physics and Biology.

It was resolved: That the applications be acceded to on condition that the candidates take the whole subject of Anatomy at the second year's examination.

*Special cases.* Application was received from a Class A student rejected in Zoology at the December examination, for permission to pass to Class B, and to sit for Biology alone in July, 1919.

It was resolved: That the application be not acceded to.

An application was received from a Class B student rejected for the third time at the December examination, 1918, for permission to pass to Class C, and to take Stable Management with the Class C examination.

It was resolved: That the application be not acceded to.

An application from a Class C student, rejected for the fifth time, at the December examination, 1918, for permission to be excused the subject of Pathology at the examination in July, 1919.

It was resolved: That the application be not acceded to.

An application was received from a Class B student, who was prevented by illness from taking his examination after the completion of a session, for permission to transfer to another College and to take the Class B examination in July, 1919.

It was resolved: That the application be acceded to.

A. B. Kerr, Class B Student, failed in Anatomy, July, 1914. Applies to be allowed, after demobilisation, to proceed to Class C, subject to passing in Anatomy, Class B, before proceeding to the Class C examination.

It was resolved: That the application be acceded to.

A. Alexander, Lt. R.A.F., Class B student, now demobilised. Applies to be allowed to sit for Class B examination in July, 1919.

It was resolved : That the application be acceded to. R. E. Glover, Lt. R.F.A., Class B student, now demobilised. Similar application.

It was resolved : That the application be acceded to. R. Smith, Class B student. No military service. Now resuming studies. Similar application.

It was resolved : That the application be not acceded to.

R. O. B. Walpole, Lt. R.F.A. Medical student. Applies (a) to be allowed to sit for Class A examination in July, 1919; (b) Alternatively, to be exempt from the first year's course if successful in passing the first Medical examination.

It was resolved : That application (a) be agreed to; That (b) be agreed on the understanding that the whole subject of Anatomy be taken at the Class B examination.

#### SCHOLARSHIPS FOR VETERINARY STUDENTS.

The PRESIDENT reported that the following letter had been addressed to the Board of Agriculture.

15562/1918.

21st December, 1918.

Sir,—In further reference to your letter of the 9th instant, I am directed by the President of the Royal College of Veterinary Surgeons to lay before you the following recommendations as to the award of Scholarships to ex-service candidates who may desire to begin or resume Veterinary training, but whose means are insufficient for them to do so:—

That an Advisory Committee be appointed, to consist of: One representative of the Board of Agriculture and Fisheries; One representative of the Department of Agriculture and Technical Instruction for Ireland; One representative of the Scottish Board of Agriculture; Five members of the Council of the Royal College of Veterinary Surgeons, not connected with the Schools; and a Chairman to be nominated by the Ministry of Labour.

That the awards should be made on the recommendation of this Committee, if possible without the definite allocation of any particular sum to each of the three countries.

It is estimated that 125 ex-service officers and men, in addition to those who are already registered as Veterinary Students, could be accommodated at the five teaching schools. Assuming that 60 such students were in need of financial assistance to an average amount of £50 per annum for four years, the total sum required for Scholarships would be £12,000.—Yours faithfully,

(Signed) FRED BULLOCK, Secretary.

(H. E. Dale, Esq.,

Board of Agriculture and Fisheries).

A letter was received from the Controller General Demobilisation and Re-settlement, stating that a District Selective Committee was being established at the Headquarters Office in each District Directorate of the Appointments Department of the Ministry of Labour, with the power to set up such Boards as may be necessary for interviewing and advising Candidates and for recommending maintenance and training grants. To insure that the interests of the Veterinary Profession are adequately represented, the Council is asked to nominate eleven members of the Profession, one for each Home District, to serve on these Committees.

It was resolved to recommend : That the following be nominated to serve on the respective Committees:—

- |               |  |
|---------------|--|
| Headqtra.     |  |
| 1. Perth      | W. Brown, M.R.C.V.S.<br>Reserve—G. Howie, M.R.C.V.S. |
| 2. Edinburgh  | Dr. O. C. Bradley, M.R.C.V.S.                        |
| 3. Manchester | H. Sumner, M.R.C.V.S.                                |
| 4. Cardiff    | Dr. J. Share-Jones, F.R.C.V.S.                       |
| 5. Leeds      | J. McKinna, F.R.C.V.S.                               |

- |               |   |
|---------------|---|

| 11. Dublin    | Prof. J. F. Craig, M.A., M.R.C.V.S.<br>Reserve—P. J. Howard, F.R.C.V.S. |

**Demobilisation.** The PRESIDENT reported that the Board of Agriculture were prepared to submit a claim for the immediate release of 100 Veterinary Surgeons over 41 years of age and required for urgent purposes. A list was therefore being prepared in the office of the names of Veterinary Surgeons for whose release urgent applications had been received, and in due course this would be forwarded to the Board at 72 Victoria Street, S.W.1. The President added that since this information had been supplied to him a public announcement had been made by the Army Council that Officers of the R.A.V.C. could not at present be released.

It was resolved that Sir J. M'Fadyean and Mr. S. H. Slocock be added to the Sub Committee to deal with questions of demobilisation.

**Recognition of Irish Welsh and Gaelic.** Communications were submitted from the Department of Agriculture and Technical Instruction for Ireland, and from the General Medical Council with regard to the recognition of Irish, Welsh, and Gaelic as approved modern languages for the purpose of preliminary educational certificates.

It was resolved to recommend that Paragraph VI Sub-Paragraph IV of the Minutes of the Committee on the 4th October 1917, be rescinded.

Educational Certificates Nos. 1748-1766, submitted from the Dublin College were approved.

**Appointment of Examiners.** The SECRETARY was instructed to advertise the Appointment of Examiners for one year to be made at the next meeting of Council.

An Application was received from the War Office for the recognition of the Special Army Certificate as qualifying for admission to a Veterinary College.

It was resolved that the Army Educational Certificate be recognised, subject to the Committee's approval of the optional subjects taken.

**Award of Prizes.** The SOLICITOR reported that as instructed he had communicated with the Privy Council with regard to the possibility of varying the Trusts of the Fitz Wygram, Walley, and Williams prizes, in order that the award of these prizes might be withheld during the period of the war. The Privy Council had expressed the view that it was undesirable to seek any such powers at the present time.

Major Gen. BLENKINSOP: I rise to ask who delegated to the Examination Committee the question of the demobilisation of officers? What that has to do with the Examination Committee I fail to see.

The PRESIDENT: I can explain that very easily. At the July Council the whole question of demobilisation was discussed. It arose on the question of scholarships, and has the question has developed it is eminently one for the Examination Committee far more than any other Committee that we have. It has to deal with the training of these men, both students in the colleges.

Major Gen. BLENKINSOP: I am afraid, sir, you have mistaken my question.

The PRESIDENT: Excuse me, General, I am making my explanation, if you do not mind. The question was specially delegated by this Council to the Examination Committee, and so it has continued.

Mr. MULVEY: You allude, I presume, to the statement made in the Report.

Major Gen. BLENKINSOP: I allude to qualified men who have passed examinations. I maintain they have nothing whatever to do with the Examination Committee. What was before the Council, as far as I remember, was the question of scholarships and assistance to be given to students and men who wished to come into the profession. I do not know if I am right or if I am in order, but I would like that to be verified.

The PRESIDENT: I have given my decision. Everything is quite in order with regard to what was referred to the Examination Committee on the authority of the Council last July. The report is now open to general discussion. You will see that there has been a tremendous amount of work done. It involves the granting of all the facilities we can to the men who have served in the army, not only to students but to officers who now wish to join the profession.

Mr. TRIGGER: I move the adoption of the reports.

Major ABSON I second that.

Mr. BARRETT: There is one word I would like to say with regard to the very lengthy reports that have just been read. One appreciates that the work has been very considerable and very extensive, but I hope that very great care has been shown in the excusing of these gentlemen from their various examinations. I should have thought it would have been wiser and safer perhaps to have insisted that whatever certificates a man might possess, provided they are not pass certificates, it would have been better to submit this man to some examination, as lenient as you please. I am not on the Examination Committee, nor was I here yesterday, but I understand that several of these students have been excused from the preliminary examinations, more particularly upon the advice of their headmasters and so forth. I can only hope that the Examination Committee has acted with very great care and with wise discretion, because it opens up a very big field. For many years we have been maintaining that the preliminary examinations should, if anything, be enhanced in value, and while I do not say that the Examination Committee is wrong in admitting all these men, I think it raises a very serious question. No doubt these are exceptional times, but I should have thought myself it would have been wiser, better, and safer to have said: "Whatever certificates you present to us, we will submit you to some test in order that we may ascertain at any rate that you possess the rudiments of education."

Mr. MULVEY: I may inform Mr. Barrett that the whole of the cases dealt with comprise those men who have served their country overseas, and it is in those cases only that any exemptions from preliminary examinations have been given. In every case all the particulars were investigated. They had to produce evidence of having received a liberal education. When that was so, and the Committee were satisfied that the evidence was sufficient for them, they granted exemption as set forth in the report of the Committee.

Sir JOHN M'FADYEAN: It is very easy, I think, for the profession outside this Council to acquire absolutely erroneous notions as to what is transacted here as a result of a discussion which amounts, on occasion, merely to a question and an answer, and it is in order to prevent any chance of misapprehension with regard to the matter which has just been raised that I now wish to say a few words. I do not know whether Mr. Barrett was aware, when he rose to make his remarks, that all the concessions to which he took exception applied to men who, as the Chairman of the Committee has just said, had been serving their country. Most of them, as a matter of fact, had been serving for four or three years; many of them had been wounded or invalided. Does Mr. Barrett suggest that in the case of these who were on the point of presenting themselves for a preliminary examination in 1914, and who patriot-

ically joined His Majesty's forces, that we should now if, on the evidence submitted to us, we are satisfied that the men in question had received a fairly good general education, nevertheless insist upon them passing the examination prescribed by us? We leave the profession outside to judge. I want it to be put beyond the possibility of misunderstanding that the Council is making no concession with regard to preliminary education except in the cases of men who have been arduously serving their country. (Hear, hear.)

The resolution for the adoption of the reports of the Examination Committee was then put and carried unanimously.

#### REGISTRATION COMMITTEE.

There is now a quorum present, and it is possible for us to deal with the cases that have come before the Registration Committee. First of all I will ask Mr. Bullock to read the resolution which was adopted by the Council at its October meeting.

The SECRETARY: The following is section 3 of the report of the Registration Committee on October 3rd, 1918: "Mr. G. N. Tomlinson, member of College, was summoned to appear on a charge of conduct disgraceful in a professional respect, namely, drunkenness when in H.M. Service, and that he was convicted of drunkenness by a general Court Martial, and in consequence dismissed the service. The Solicitor stated that Mr. Tomlinson had written that he did not intend to enter any defence or to attend the meeting. The Solicitor read the official record of the Court Martial held 3rd April, 1917, from which it appeared that he was charged with (1) Drunkenness, (2) Drunkenness, (3) An act to the prejudice of good order and military discipline, and pleaded guilty to (1) and (2), but not guilty to (3). The finding was not guilty to (3), and the sentence to be dismissed from H.M. Service. The Committee find the charges proved."

The PRESIDENT: That report was passed at the last Council meeting in October, and consequent on it I now move "That the name of Mr. George N. Tomlinson be removed from the register of Veterinary Surgeons."

Mr. LAWSON seconded the motion, which was then put and declared by the President to be carried.

The PRESIDENT: You have adopted the minutes of the meeting of the Registration Committee held yesterday, and consequent on that I now move: "That the name of a member in question be removed from the register of Veterinary Surgeons."

Mr. TRIGGER: I beg to second that.

The PRESIDENT: The motion is carried, 15 voting for and 2 against.

The SECRETARY: The Charter says: "It shall be lawful for any meeting of the Council, at which not less than two-thirds of the members shall be present, and with the consent of three-fourths of the members so present, but not otherwise, to remove the name of any member from the Register of Members of the College." Twenty-two members of Council are present, so that 17 must vote for the motion, otherwise it is not three-fourths of the members present.

Mr. THATCHER: The words are very clear. Three-fourths of the members present must vote in favour of the resolution.

A MEMBER: I think the vote should be taken again because there seems to be some doubt about it. I think some hands that were held up were not seen.

The PRESIDENT: I will take the vote again. Those in favour of the resolution, that the name be removed from the register of Veterinary Surgeons, please signify.

The resolution was then put, when 15 members voted for and 4 against.

The PRESIDENT: The resolution is not carried.

Prof. GAIGER : Are we to take this vote without any discussion on the matter? Some of the members here to-day were not present at the meeting of the Registration Committee, and did not hear the case at all.

The PRESIDENT : That is their fault ; we cannot drag them here.

Prof. GAIGER : I do not see how they can vote if they were not present at the meeting of the Registration Committee.

The SOLICITOR : If you will look at the Act you will see that the Council proceeds upon the report of the Committee, and that report has been presented.

Prof. GAIGER : But the report did not suggest that his name should be taken off : it merely reported that they found the charges proved.

The SOLICITOR : They have no power to do so.

The PRESIDENT : The Committee cannot do that. It is only the Council that can do that. The Committee found the charges proved.

I have now to move that the name of Mr. A. E. Webber be restored to the register of Veterinary Surgeons.

Mr. McKINNA seconded the motion, which was carried.

Sir JOHN M'FADYEAN : May I add a word about the report of the Registration Committee before we proceed to the next business? I should like to call the attention of the Council to the enormous importance as a precedent of what has just happened. The name of one member convicted of conduct disgraceful in a professional respect has been struck off the roll, and the name of another member convicted of what, on the face of it, was a more severe crime, has not been struck off. I do not know what the other members of the Council may feel, but my feeling now is that the Council has ceased to recognise drunkenness on duty as a crime, and that we can never in future strike members off the roll for that offence. I do not want to review the case, but I think the gravity of what has just happened ought to be pointed out.

Major-General BLENKINSOP : With regard to what Sir John M'Fadyean has just said, I would like to make this explanation with regard to the two cases which are before you.

The PRESIDENT : I do not think you can go into that. If you like to say something about the action of the Council, well and good.

Major-General BLENKINSOP : It is in connection with the action that has taken place at this meeting that I desire to make a few remarks. Sir John M'Fadyean has been allowed to make a statement on the very point on which I wish to make a statement. If there is any difference between us, and if you will not allow me to make a statement, I will sit down.

The PRESIDENT : Yes, I will allow you to make a statement on that point, on the action of the Council, but not to review the case.

Major-General BLENKINSOP : I was not reviewing the case. The whole point is this. In these two cases you have one that is a very serious case—

Mr. BARRETT : I rise to a point of order. I submit that the whole of this discussion is irregular and ought not to be permitted.

Sir STEWART STOCKMAN : I think I am in order in moving that the names of the voters one way or the other be recorded.

Mr. TRIGGER : I second that.

Dr. SHARE-JONES : I suggest that that cannot be done.

The PRESIDENT : I think this is irregular. I decide in favour of Mr. Barrett's point of order, and accordingly we will proceed to the next business.

#### ANNUAL FEE COMMITTEE.

Sir JOHN M'FADYEAN read the following reports of the Annual Fee Committee, held on December 5th, 1918, and the 9th of January, 1919.

December 5th, 1918.

It was resolved that Sir J. M'Fadyean be appointed Chairman of the Committee for the ensuing year.

*V.S. Act Amendment Bill.* The Amendment Bill was considered and the following alterations were approved :—

The fourth clause of the preamble to stand first.

Section 2 to be renumbered 3 and Section 3 to be renumbered to 2.

Clauses (1) and (2) of Section 3 to be altered to read as follows :—

3(1). An annual fee of one guinea shall be payable on the first day of April in each year or such other date as the Council may from time to time determine by every member of the Royal College of Veterinary Surgeons save as excepted in Sub-section (4) hereof, such fee to be paid to the Registrar of the Royal College of Veterinary Surgeons on or before the thirtieth day of April in each year, or such other date as the Council may from time to time determine. The Registrar shall cause a copy of the Register of Veterinary Surgeons to be posted to each member whose name and address appear in such Register free of all cost.

(2). If the annual fee of any member shall not have been paid on or before the thirtieth day of April in any year or such other date as may have been fixed by the Council as aforesaid, the Registrar shall send to such member by post at the address given in the Register of Veterinary Surgeons for the time being, or to any other address of which written notice shall have been given by such member to the Registrar, a notice requiring payment, and if such payment shall not be made within one month from posting such notice a final notice shall be sent to such member by registered post.

*Memorandum.* The following memorandum to be prefixed to the Bill was approved.

#### VETERINARY SURGEONS ACT (1881) AMENDMENT BILL MEMORANDUM.

This Bill, which was introduced in 1911, 1912, 1913, 1914, and 1915, is for the purpose of empowering the Royal College of Veterinary Surgeons to impose a fee of £1 1 0 on all members of the College (with certain exceptions).

The present income of the College is not sufficient to enable it to carry out the duties imposed upon it by the Veterinary Surgeons Act (1881) and its various Charters.

Since the outbreak of the war subscriptions of a guinea a year have been paid voluntarily by a large number of members in order to enable the College to carry on its work until such time as the Bill can be passed into law. At the present time over 1100 members out of 3300 on the Register are thus voluntarily subscribing to the funds of the College.

The measure is necessary in order to place the College on a satisfactory financial basis and to enable it to meet the new demands which will be made on it during the period of reconstruction.

The Bill has been submitted to, and approved by, the Privy Council, and is supported by the general body of the profession.

In the recent Report of the Departmental Committee on the Public Veterinary Services [Cd. 6575, (1913)] the following statement is made :—

"The lack of funds seriously hampers the work of the college. With a view to improve its financial position the College is seeking power in a Bill now before Parliament to charge an annual fee of one guinea on each of its members and fellows. This Bill we understand has the support of the great majority of the profession, but so far little progress has been made with its consideration. We are of opinion that the College is performing work of great national importance, and

that its efforts to maintain a high standard of veterinary education in this country are worthy of every encouragement."

Section 4 is desired for the purpose of putting a stop to quackery by Companies registered under the Companies' Acts and who cannot now be punished. Section 19 of the Interpretation Act 1889 which is to the same effect as the Clause asked for is not retrospective.

It was resolved that the Bill as amended be approved and submitted to Privy Council.

That every endeavour be made to have the Bill introduced in the new Session of Parliament as a Government measure.

*Amendment Bill.* Copies of the Bill as revised at the previous meeting were submitted, and it was resolved

That the last Clause of Paragraph 2 (1) be altered to read as follows—"On receipt of such fee the Registrar shall cause to be posted to the member paying the same a copy of the Register of Veterinary Surgeons free of all cost."

The SOLICITOR reported that he had received the formal approval of the Privy Council to the Bill in its present form.

It was resolved that the Chairman be authorised to take such action as may appear to him necessary in order to secure the adoption of the Bill as a government measure.

That a special Sub-Committee be appointed, consisting of Sir John M'Fadyean, Sir Stewart Stockman, Mr. W. F. Barrett, Mr. T. S. Price, Mr. S. Slocock, with executive powers to deal with any matter arising during the progress of the Bill through Parliament.

Sir JOHN M'FADYEAN: I move that the two reports be received and adopted.

Major ABSON seconded the motion, which was carried unanimously.

#### HONOURS AND PRIZES COMMITTEE.

Mr. BANHAM read the following report of a meeting of the Honours and Prizes Committee, held on January 9th, 1919.

*Williams Memorial Prize.* The report of the Auditors was submitted showing Mr. C. A. Ewing of the Royal Veterinary College of Ireland, Dublin, secured the highest number of marks, namely 126, in Class D Examinations in 1918.

It was resolved to recommend that the Williams Memorial Prize for 1918 be awarded to Mr. C. A. Ewing.

*Walley Memorial Prize.* The report of the Auditors was received showing that Mr. W. G. Jones, and Mr. C. P. Neser, of the Royal Veterinary College of Ireland, Dublin, were bracketed first, with the highest number of marks, 113, in the Written Examinations in Pathology, Materia Medica and Hygiene, in December 1917 and July 1918.

It was resolved that the Walley Memorial Prize for 1918 be divided equally between Mr. W. G. Jones, and Mr. C. P. Neser.

On the motion of Mr. Banham, seconded by Mr. Packman, the report was received and adopted.

#### PUBLICATION, LIBRARY, AND MUSEUM COMMITTEE.

Mr. SHARE-JONES read the following report of a meeting held on 10th January:—

*Presentations to Library.* The Secretary reported that since the previous quarterly meeting the following presentations had been made to the Library.

Bulletin of the Institute for Infectious Diseases of Animals, Japan, No. 1, 1913. Über das Askaron, einen toxischen Bestandteil der Helminthen besonders der Askariden und seine biologische Wirkung (mittellung I, T. Shimamura u. H. Fujii, July, 1917. On the Toxic Constituents in the bark of Robinia pseudacacia L., Report 1., B. Tasaki and U. Tanaka, May, 1918. Über

die Serodiagnose der Schwangerschaft bei Pferden und Kühen, mittelst des Abderhalden'schen Dialysierfahrens T. Shimamura u. S. Matsuba, June, 1917. Über die proagglutinoidähnliche Reaktion durch Haemoglobinlösung, von K. Tagawa, May, 1918. Über die Bedeutung des Salzes bei der Agglutination, von K. Tagawa, May, 1918. Weiters Studien über die Bedeutung des Salzes bei der Agglutination und ihre Anwendung zur Serodiagnostik des Rotzes von K. Tagawa, May, 1918 (The last six reprints from the Journal of the College of Agriculture, Imperial University of Tokyo).

Delabere Pritchett Blaine, Outlines of the Veterinary Art; 2 vols, 1802 (first edition), presented by the Secretary.

First 10 vols. of *Journal of Comparative Pathology and Therapeutics*, presented by S. Beeson.

*Annual Reports:* C.V.D., Bihar and Orissa, 1917-18; C.V.D., Madras, 1917-18; V. Dept., Rangoon, 1917-18; Vet. Director General of Canada, 1916-17; C.V.O. Board Agriculture and Fisheries, 1917; New York State V. College, 1916-17; Lister Institute of Preventive Medicine.

*Calendars:* University of Edinburgh, 1918-19; University of Liverpool, 1918-19; Royal Coll. of Surgeons of England, 1918; Ontario V. College, 1918-19; Indiana V. College, 1918-19.

*Periodicals:* The Journal of the Board of Agriculture and Fisheries; The Scottish Journal of Agriculture; The Journal of Comp. Path. and Therapeutics; Revue de Pathologie Comparée; Journal of Physiology (per Sir F. Smith); The Vet. Review; The Vet. Journal; The Vet. Record; The Vet. News; The Rhodesia Agric. Journal; New Zealand Journal of Agric.; Journal of Department of Agric., Melbourne, Australia; Bloodstock Breeders' Review; British Medical Journal (per Dr. Bradley); Medical Journal of Australia; Educational Times; N.Y. University Veterinary Bulletin; N.Y. State Vet. College Alumni News.

It was resolved: That a vote of thanks be accorded to the respective donors.

*Register, 1919.* The Secretary was empowered to approve the form of advertisements for the new edition of the Register.

Dr. SHARE-JONES: One very interesting presentation is Delabere Pritchett Blaine's "Outlines of the Veterinary Art." Our Secretary evidently has been ferreting around, and has succeeded in discovering two volumes of the original edition of this work which was published in 1802, and he has presented the two volumes to the Library. I move that the Report be received and adopted.

Mr. MCKINNA seconded the motion, which was carried unanimously.

#### SPECIAL MEETING OF COUNCIL.

Immediately following the quarterly meeting, a Special Meeting of Council was held at which the President, Mr. F. W. Garnett, took the chair, and the same members were present as at the quarterly meeting.

*Minutes.* The minutes of the previous meeting, which had been printed and circulated, were taken as read and confirmed.

#### ADDITION TO BYE-LAW 61.

The PRESIDENT: I beg to move "that the following addition be made to Bye-law 61.—After the first clause to add the words: "together with a copy of his birth certificate."

Major ABSON seconded the motion, which was carried unanimously.

#### ADDITIONAL BYE-LAW.

The PRESIDENT: I beg to move the adoption of the following additional bye-law to precede Bye-law 61:—

"In any special circumstances arising in connection with the war, exemptions or other concessions may be granted by the Council on the recommendation of the Examination Committee to any person who has served in His Majesty's Forces since the 3rd day of August, 1914."

Mr. LAWSON seconded the motion, which was carried unanimously.

#### ALTERATION TO BYE-LAW 63.

Prof. GAIGER: I beg to move the following alteration to Bye-law 63:—Paragraph *a* to read:—"Pathology. A course of not less than 80 lectures on the pathology, bacteriology and protozoology of the domesticated animals." Paragraph *b* to read:—"Practical pathology. A practical course extending to not less than 40 hours' instruction on the pathology, bacteriology and protozoology of the domesticated animals." The object of that is merely to bring the wording more up to date.

Mr. BANHAM: I second that.

Sir JOHN M'FADYEAN: I should be glad if Prof. Gaiger will explain to those of us who are asked to support him—what is the real motive for effecting this alteration?

Prof. GAIGER: The real motive occurred to me before I saw that any alteration had been made to a similar purport in another part of the register. That had already been altered under the heading of Examinations, Examination C. You will there notice exactly the wording that I have given here, although it had previously occurred to me that this would be very much better than the antiquated words of "morbid anatomy," which is practically a repetition of "pathology." The old wording is a repetition, the two words meaning practically the same thing.

The PRESIDENT: The old wording is "morbid anatomy and pathology: a course of not less than 80 hours lectures on the morbid anatomy and pathology (including bacteriology and protozoology) of the domesticated animals."

Prof. GAIGER: The alteration has already been made on page 78 of the Register at a previous Council meeting, and I take it that the intention was the same as mine, to make the wording more accurate.

Sir JOHN M'FADYEAN: But I am not prepared to admit that it is more accurate. My contention is that pathology covers bacteriology and protozoology, and that this is not superior to the original term, morbid anatomy and morbid pathology, and that there is an actual danger in amplifying and extending the word "pathology" as if bacteriology were not pathology. It is perfectly clear that it is only the effects of bacteria in inducing disease that the examiners are entitled to ask any questions about in connection with the examination in Class C, that is to say, it is only the pathological effects of bacteria, and similarly with regard to protozoa. One practical effect that is likely to follow, I am afraid, is that we shall have one of the examiners devoting himself entirely to questions of bacteriology and protozoology, and this may lead to students being expected to have a knowledge of bacteriology and protozoology that is not quite reasonable. I personally should like it simply left as "pathology," but I do not think the matter is of great importance, and I do not think the reason assigned by Prof. Gaiger is a good one for altering it. Besides, I may point out to him that he has introduced the word "bacteriology" himself.

Prof. GAIGER: Where do you mean?

Sir JOHN M'FADYEAN: Does this mean that there is to be a special course in bacteriology by a special teacher?

Prof. GAIGER: As it stands at present, they are being examined in one thing, and another thing is laid down in the bye-law. In Bye-law 63 a certain thing is laid down, and on page 78 they are being examined in another thing, according to what you have just stated.

Sir STEWART STOCKMAN: I think that is so, but is not the proper course to adopt to change back to the other thing? I feel exactly what Sir M'Fadyean has expressed, that when you talk of protozoology and bacteriology it is quite a misnomer in medicine unless you are talking of pathology, or the bearing of these on pathology. It would be quite ridiculous to expect our students, or to assume that our students, can be taught protozoology or bacteriology in the time. What they are taught is medical or veterinary bacteriology, or veterinary protozoology in relation to pathology. It is really pathology they are taught. I do not think there is any great difference of opinion between us, but I think what Prof. Gaiger means is the pathology of protozoal diseases and the pathology of bacteriological diseases. Am I right?

Sir JOHN M'FADYEAN: That is not quite correct. I find that in Bye-law 63, which it is sought to amend, the words are different, and I should raise no objection to them. But in Bye-law 63 the only subjects mentioned are morbid anatomy and pathology, and then in parenthesis or brackets "including bacteriology and protozoology," specifying that those parts of pathology are not to be omitted.

Prof. GAIGER: Surely pathology includes morbid anatomy! Why use the words "morbid anatomy" at all?

Sir JOHN M'FADYEAN: I ask another question in reply to that: Why introduce the word "bacteriology" and take it out of the brackets?

Mr. SUMNER: May we know why the subject is referred to in different terms in the curriculum from what it is in the examination?

The PRESIDENT: It should be the same in both cases.

Dr. SHARE JONES: Looking at it from the point of view of an outsider, I may say there was a time when pathology was regarded as being a term which included the whole lot, and there was one chair which covered all the subjects. But as these subjects have developed, we find that chairs in bacteriology alone have been instituted, and latterly, within our time, chairs of protozoology alone have been instituted. So that there is something to be said for the attitude which Prof. Gaiger has taken up.

The PRESIDENT: I will now put it to the vote.

Sir STEWART STOCKMAN: If we vote against it, we cannot modify it as set out in the notice of motion?

The PRESIDENT: No.

Mr. MCKINNA: This is really a matter for the experts. I think they should make up their minds what they want, and then the Council will agree with them.

Prof. Gaiger's motion was then put and lost, 6 voting for and 8 against.

#### ALTERATION TO BYE-LAW 62A.

The PRESIDENT: The next item on the agenda is an alteration to Bye-law 62A, which will be moved by Mr. MULVEY. This bye-law has taken a great deal of drafting. It has been discussed by the Council on two or three occasions. We have had legal advice and done everything we can to try to incorporate our meaning into it.

Mr. MULVEY: I beg to move that Bye-law 62a be altered to read as follows:—"(1) A student who has obtained a degree in Arts, Science or Medicine, or a degree or diploma in Agriculture granted by a University situate within the United Kingdom, or by any other body whose degree or diploma in Agriculture is approved for the time being by the Council on the recommendation of the Examination Committee, or the diploma of Licentiate of one of the Royal Colleges of Surgeons, or of one of the Royal Colleges of Physicians, and who in procuring any such degree or diploma passed an examination in Chemistry and also in Biology,

Zoology or Botany, shall be exempted from his A or first professional examination, and the bye-laws and regulations in respect thereof, and shall be entitled in all respects to the rights and privileges which the passing of such examination ordinarily confers, provided always that such student so exempted shall be examined in the whole subject of Anatomy in the Class B examination. (2) A student possessing a degree or diploma of a like import or denomination to one of those enumerated in paragraph (i) hereof, but granted by a University or other examining or licensing authority other than those mentioned in paragraph (i) shall, if the Council declare its sufficiency for exemption, thereupon become entitled in all respects to such exemptions, rights and privileges as are defined in paragraph (i) of this bye-law."

Lieut.-Col. BRITTLEBANK: I second that.

Dr. SHARE-JONES: I have an amendment here which I have drafted, but gather from your ruling on the last occasion that you will not accept an amendment?

The PRESIDENT: I am afraid I cannot.

Dr. SHARE-JONES: Then I intend to vote against the resolution. I am very sorry, after the pleasant ceremony which has occurred this afternoon, but I shall have to vote against the Chairman of the Examination Committee.

Mr. MULVEY: Don't mention it. (Laughter).

Dr. SHARE-JONES: You will understand that I am voting against the motion, and not against him. (Hear, hear). We are up against a serious proposition this time, whatever the previous one may have been. There is no one round this table keener than Mr. Mulvey for a high standard of education. He has stood by it all along, and I cannot, for myself, come to any other conclusion than that he has drafted this most comprehensive regulation, quite the most comprehensive that I have ever seen in any set of regulations anywhere, without informing himself sufficiently as to the standard of education required in the various qualifications laid down here. There are qualifications mentioned here which are undoubtedly excellent qualifications, but there are others of a very low standard indeed. There are others, again, which I will defy anybody to define the standard of at all. I think Mr. Mulvey has attacked this very difficult problem in the wrong way altogether. What he should have done was this: he should have classified these various qualifications, and given us two or three sub-clauses. For instance, there is the question of preliminary education which Mr. Mulvey, above everyone, is keen about. Surely there is one type of qualification he should have dealt with at once, and that is the question of the degree. He should have said that he would have given exemption to a candidate for a degree who had passed in certain requisite subjects in the examination for that degree, and that would mean that we should know and be sure that the man had passed a matriculation examination. There is no question about it that that man would have had a higher standard of preliminary education than we demand, and that value would be carried by the certificate of matriculation itself.

Then there is another thing. We grant exemption to candidates—and I am very pleased we do—on the ground that they have a certain knowledge in certain subjects which we require a man to know. That refers to the subjects of the first year—chemistry, elementary physics, botany, zoology, and junior anatomy. And yet we have the astonishing feature of this regulation that it is proposed to grant exemption to candidates who may not have done anything at botany and at physics. I think it grossly unfair to the men who take the four subjects—to grant exemption to any candidate who takes only two. Under these circumstances I have no other option but to vote absolutely against the motion.

Mr. MULVEY: Then you will vote absolutely against what you said you would support at the last meeting.

Dr. SHARE-JONES: Not at all. It has never been put to the vote.

Mr. MULVEY: I am perfectly aware of that; but you and I talked this over at the last meeting, and you saw this at the last meeting.

Mr. SHARE-JONES: I saw it, but it has never been before us to vote upon it.

Mr. MULVEY: All right, never mind. (Laughter). I contend that your statement is not correct. First of all, it is for students who have obtained a degree in arts, science or medicine, or a degree or diploma in agriculture. You stated just now that there was nothing shown here, or there was no evidence given that a degree had been obtained.

Mr. SHARE-JONES: But you are compelling a student to go on to his degree before you give him exemption. You will not exempt a good student when he has passed in the subjects, and I claim that you are driving that student out of the profession rather than encouraging him to come in. That is what you are doing. A student starts on a degree that takes six years to get: he takes these subjects that we require in the first year; he will never touch them again, and, according to your regulation, you will not exempt that man until five years after he has passed. Is that encouraging him to come in?

Mr. MULVEY: I do not agree with you in your interpretation of the wording of the clause.

Mr. SHARE-JONES: We might go so far, speaking in jest, but I took the way in which it was put by yourself as distinctly personal.

The PRESIDENT: He must obtain a degree.

Mr. SHARE-JONES: Yes, he must obtain his degree.

The PRESIDENT: May I clear up the point that is at issue? Dr. Share-Jones maintains that a man who has passed his first examination in arts, science, medicine or the diploma or degree of agriculture by a university should be granted the same exemption by this Council for his first examination. On the other hand, Mr. Mulvey says that he must have proceeded to his degree before he can be granted exemption, and that is what this body has always carried out up to the present time.

Mr. SUMNER: This matter was put before us some years ago.

Dr. SHARE-JONES: With regard to the point that has been raised, a man with a degree might not have taken any physics, and he might not have taken any zoology, and still you exempt him. You push the man who has taken chemistry, physics, botany and zoology up to the degree standard, and the only standard which he will be required to attain, and if you pursue that, is five years' further study.

Mr. BARRETT: You are wrong.

Dr. SHARE-JONES: I should like, if I may, to read the amendment I intended to propose, but which the President rules is impossible: "That candidates who have passed in chemistry and physics, together with biology or botany and zoology, at one of the examinations for a degree in a British university shall be exempt from the courses of study in these subjects and from the A examination, but such candidates shall be required to present themselves in the whole of anatomy at the Class B examination." It was my intention to move that, but I cannot do so. That is what I would like to substitute for this clause.

Sir JOHN McFAYDEAN: I would like to recall to the Council what I believe was the original motive which led to the framing of bye-law 62a. It was that an attempt should be made to induce as large a number as possible of university graduates, particularly those who held degrees in science, to become members of the Royal College of Veterinary Surgeons. I think I am right in saying that.

Dr. SHARE-JONES: And you were recommended also by that same Committee to deal with men who had attained an intermediate stage.

Sir JOHN M'FADYEAN: Recommended by whom?

Dr. SHARE-JONES: By that Committee whose report led up to this.

Sir JOHN M'FADYEAN: Nothing of the kind.

Dr. SHARE-JONES: It arose directly out of that Committee's report.

Sir JOHN M'FADYEAN: No, indeed it did not. I can only say I have no recollection of it.

Dr. SHARE-JONES: I have.

Sir JOHN M'FADYEAN: At any rate, that was the reason. Somebody may have suggested—I think very likely if you were on the Committee you may have suggested—an entirely different question. I do not know, but I should think probably the view that you are now putting forward is one that you have held consistently all along.

Dr. SHARE-JONES: Yes.

Sir JOHN M'FADYEAN: But I hold it to be an absolutely separate point of view. It is that the students who are studying arts, or science, or medicine, but have not qualified in anything at all, are to be granted exemption by us in particular subjects because they have passed these examinations.

Dr. SHARE-JONES: In those subjects.

Sir JOHN M'FADYEAN: In those subjects, but have not qualified.

Dr. SHARE-JONES: In those subjects they are qualified.

Sir JOHN M'FADYEAN: They are not qualified in the sense in which we are using the word.

Dr. SHARE-JONES: They will never qualify any further in those subjects.

Sir JOHN M'FADYEAN: I decline to be drawn into a quibble of that sort, because it is absolutely a quibble.

Dr. SHARE-JONES: It is not.

Sir JOHN M'FADYEAN: You are using the word "qualification" in one sense, and I am using it in the ordinary sense, the sense in which we say a student is qualified here, that is to say he has taken the diploma of the Royal College of Veterinary Surgeons. Perhaps a good deal could be said for deciding in favour of the view put forward by Dr. Share-Jones, but I hold it is a perfectly distinct issue, and I think Dr. Share-Jones quite wrong in supposing that all the arguments with regard to that are on his side. I do not admit it. But the question here is, what concession shall be made to those who have taken a degree or diploma, and not what concession is to be made to those who are only in the position of students. I should like to deal especially with one of the points made by Dr. Share-Jones. He asks us to believe that if a student—a medical student for instance, has passed in the subjects of chemistry, physics and biology, that he is as much entitled to a concession from us with regard to those subjects as if he had proceeded with his studies and qualified in medicine. I dispute that altogether. There is no comparison at all between a fully qualified medical man and a man who has only passed his first professional examination in medicine. I merely mention that to show that the two cases are not really absolutely parallel—that one might support the one and refuse to support the other. I do not want to occupy the time of the Council, but I should like to ask Dr. Share-Jones to specify to us what are the diplomas or degrees referred to in this amendment of the bye-law that he places in such an exceedingly low category.

Dr. SHARE-JONES: In regard to that point I must decline to do what you ask, but I have a letter in my pocket, which is confidential to me, where there is no preliminary examination at all asked for.

Sir JOHN M'FADYEAN: A University.

Dr. SHARE-JONES: Yes; a University.

Sir JOHN M'FADYEAN: The remedy for that is that Dr. Share-Jones should bring the facts to the knowledge of the Council, and we will, I venture to say, amend the bye-law again so as to exclude that particular University diploma.

Dr. SHARE-JONES: I suggest that that should go down lower in this regulation, which would entitle the Committee to do what you say.

Sir JOHN M'FADYEAN: That, I thought, was what you meant. What Dr. Share-Jones meant, apparently, was that we might have an application with regard to certain diplomas.

Dr. SHARE-JONES: Exactly.

Sir JOHN M'FADYEAN: Which he holds are of a low category; but I call your attention to the fact that, except in the case of University qualifications, the bye-law is only permissive. The Committee has to approve of them.

Dr. SHARE-JONES: If you put diplomas down a little lower, among the permissive set, you are perfectly safe, and you could then deal with any one that came up, but a diploma and a degree are different things altogether.

Sir JOHN M'FADYEAN: My point is this, that we are not really in any danger of accepting any of these qualifications of such a disgracefully low character, because they have each to be examined, and the decision will be on its merits. No doubt the Committee will enquire into the subject and find out what is really the case. I do not hold any very strong views on the subject, because I do not think we are ever likely to induce or exclude graduates in science by this alteration. In my opinion the Council will do no harm in passing it.

Dr. SHARE-JONES: Even if a man has not taken two out of the four subjects.

Sir STEWART STOCKMAN: You have mentioned something about a Committee. I take it you meant the Committee on the Veterinary Services?

Dr. SHARE-JONES: I did.

Sir STEWART STOCKMAN: I have had a great deal to do with that in the way of carrying into effect the recommendations made by it, and I assure you that what you stated was quite incorrect. What the Committee said was this—

Dr. SHARE-JONES: I challenge you yourself—Will you put those Minutes on this table to discuss at the next meeting?

Sir STEWART STOCKMAN: We will get the Report, if you like, but at present I am entitled to say that the recommendation was that they should have scholarships to offer to distinguished graduates in science, and graduates in other suitable degrees, to encourage them, particularly honours graduates, to enter the veterinary profession after they have qualified at the university, and, *vice versa*, that there should be scholarships for men who had qualified at the veterinary schools to take degrees in science. That was the recommendation.

Dr. SHARE-JONES: That was one. But was there not a further one?

Mr. BARRETT: There is no doubt that when this question came before the Examination Committee it decided, after careful deliberation, that the students should take a degree before having any of these exemptions granted to them. There can be no harm, therefore, in our passing this bye-law to-day. But I must say I am forcibly struck with Dr. Share Jones's contention, namely, that a student who has passed, say, at the London University, the preliminary scientific examination, who may have equipped himself thoroughly in chemistry, botany, zoology, or any of these subjects, should be entitled to exemption by us and be admitted a student by the Royal College of Veterinary Surgeons. If that were agreed by the Council, we could easily pass this bye-law to-day, and then within a period

of three or six months Dr. Share Jones could draft an amending bye-law which the Council might be inclined to accept.

Mr. BANHAM: May I ask, if a gentleman took his Bachelor of Arts in anything but science, would you be prepared to let him go on to the second year's course?

Mr. BARRETT: He gets exemption provided he has passed in those subjects.

The PRESIDENT: I think it would have prevented all this discussion if I had pointed out that this only applies to exemptions that we propose to give to holders of a degree. Dr. Share-Jones is quite at liberty to bring forward any other resolution as an addition to it.

The resolution was then put and carried, one member, Dr. Share-Jones, voting against.

#### CONFIRMATORY MEETING.

It was unanimously agreed that the confirmatory meeting should be held on Friday, the 24th January, at 4 o'clock.

*Vote of thanks to the President.* On the motion of Mr. Packman, seconded by Mr. Barrett, a very hearty vote of thanks was accorded to the President for his conduct in the chair, which the President briefly acknowledged, and the meeting terminated.

#### CENTRAL VETERINARY SOCIETY.

We are specially requested to intimate that on Thursday February 6th, after the monthly meeting of the Society, a dinner will be held at The Holborn Restaurant, Duke's Room, at 7 p.m. Members of the profession on military service wishing to attend will be cordially welcomed.

Tickets 7/6 exclusive of wines.

Those intending to be present should intimate the fact to the Hon. Sec. Mr. Hugh A. MacCormack, 122 St. George's Avenue, Tufnell Park, N. 7, not later than January 31st, in order that adequate arrangements may be made.

#### ARMY VETERINARY SERVICE

##### ORDER OF THE BRITISH EMPIRE.

The King has been pleased to give orders for the following appointments to the Most Excellent Order of the British Empire, for valuable services rendered in connexion with military operations in various Fields (Dated Jan. 1, 1919):—

##### MEMBERS (Civil Division).

\* \* \* \* \*  
John Ewing Johnston, Esq., Veterinary Officer in Charge, Remount Depot, Belfast.

##### THE MILITARY CROSS.

War Office, Jan. 11.

The King has been pleased to approve of the award of the Military Cross to the following in recognition of his gallantry and devotion to duty in the Field:—

Capt. L. E. L. TAYLOR, 3rd Mob. Vet. Sec., Can. A.V.C.—

During an attack he at great personal risk from shell fire superintended the removal of all sick and wounded animals from the lines of his section to a more protected area. He was wounded while doing so, still he remained on duty, repeating his endeavours to scatter his animals so as to lessen the risk of casualties. The result was that no casualties occurred within his unit, though a number of men and animals were killed and wounded in close proximity. A great deal of first-aid work was accomplished by him in the forward areas.

#### Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Jan. 11.

#### REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Capt. to be actg. Maj.:—R. W. Mellard, D.S.O. (Nov. 20, 1918).

Jan. 13.

Capt. R. M. Bamford is secd. for duty with Egyptian Army (Oct. 27, 1918).

Jan. 16.

Temp. Capt. N. B. Green resigns his commn. (Jan. 17), and retains the rank of Capt.

#### SPECIAL RESERVE OF OFFICERS.

Jan. 14.

Capt. C. R. Roche to take rank and prec. in his Corps and in the Army as if his appt. as Capt. bore date July 17, 1916.

#### TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Jan. 15.

Maj. C. H. Golledge is retired, having attained the age limit (Jan. 16), and retains the rank of Maj., with permission to wear the prescribed uniform.

#### COCCIDIOSIS IN THE RABBIT.

*To the Editor of the "Veterinary Record."*

Sir,—My attention has been directed to a letter appearing in your issue of Jan. 11th from Sir John M'Fadyean criticising my communication to the Central Veterinary Society on "Coccidiosis in the Rabbit." In view of the tone of that letter, I absolutely refuse to be drawn into any discussion on the subject in the press, at the direction of the writer. The agenda of the meeting in question was published, and since Sir John was so keenly interested in the subject and held such pronounced views thereon, it is a matter for regret by the whole of the profession that he was prevented from attending and making those views public in the proper manner. Discussions are welcomed at such meetings as that at which the paper was read, especially from such authorities as Sir John, and one regrets that the members were deprived of such an intellectual feast. Sir John has at any rate the satisfaction of knowing that his timely intervention will save the reputation of British veterinary research, and will prevent readers abroad inferring that "the study of coccidiosis of the rabbit has been sadly neglected in this country." I have no intention whatever of entering into what must necessarily be a lengthy controversy in order that Sir John may have an opportunity of making his views known by other than the usual channels of publication. I make Sir John a present of any satisfaction which he may obtain from my refusal to discuss the matter further at present and under these conditions. I absolutely refuse to have any line of action dictated to me by Sir John, and I can only regard the courses which he suggests as open to me, and his self-appointed representation of the Central Society, as unwarrantable presumption.

One awaits with impatience the publication of the results of Sir John's researches with regard to the disease in question.—Yours faithfully,

J. B. BUXTON.

Hognose,

Wrotham, Kent, Jan. 14, 1919.

#### THE COUNCIL OF THE R.C.V.S.

Sir,—One remark in the letter of "Reform," in your issue of January 4th, may lead to misunderstanding unless immediately corrected. He quotes the published results of the Final Examination of students from

London, Liverpool, Glasgow, and Dublin (omitting all reference to the other three classes), and says:—"I understand that examiners had to travel to these places of decentralisation. Why? The only answer I can give is: the Schools decide these things."

The fact is, the decision as to where the examinations are to be held is not in the hands of the schools. Indeed, whenever they have been asked to do so in recent years, the schools have arranged to send their students to any centre where an examination was being held, thus saving considerable expense to the R.C.V.S.

Neither is it in the power of the Council altogether to decide as to the number of centres of examination. The matter is settled by the Veterinary Surgeons Act, 1881. Section 4 reads:—"The R.C.V.S. shall be bound to make provision, in the manner permitted by their Charters, for the examination in England . . . and in Scotland . . . and in Ireland . . ." etc.

It is thus obvious that the R.C.V.S. is compelled by law to arrange for at least three centres of examination.

Yours faithfully,

FRANK W. GARNETT, President.

R.C.V.S.,

10 Red Lion Sq., W.C., Jan. 13, 1919.

Sir,—To be contributions of any value to the profession the correspondence occupying your columns recently should contain something more than mere abuse.

Accusations levelled at gentleman of recognised probity and integrity need to be supported with something more than "envy, hatred, malice, and uncharitableness." To suggest "axes to grind" and speak of "take all and give nothing" shows a total ignorance of the position and work of councillors who can have nothing to gain but the satisfaction of having served the profession they love, and must invariably be out of pocket, in time and in hard cash, in leaving their own affairs and travelling—often long distances—to give their best efforts on the Council.

A councillor's value is not to be measured by his oratory in the chamber of the R.C.V.S. or in other and greater assemblies, but by the conscientious labour he puts in at Committees, where the work is laborious, often tedious, and devoid of glory, and unseen by the electors. The so called silent men find their tongues on Committees and demonstrate how "a still tongue makes a wise head." They have been good listeners in the general assembly, and having digested the subject, bring their strong common sense and practical knowledge to bear when it is most wanted and most likely to have effect.

There have been other occasions in the past when a bright meteoric star has come into the veterinary firmament and dazzled the voter with promises of cleansing the Augean stable; but contact with the realities, and the discovery of his own ignorance of Acts and Charters, has usually made him seek a back seat after one splendid effulgence by way of justifying his election. Now and again a sensible man, believing that an infusion of new blood is essential to the preservation of the body politic, has employed extravagant language in his new-found zeal, has honestly regretted his fulminations against tried and trusty Councillors, and has become a useful member.

Just as "every country has the government it deserves," so does a profession; and it is in the hands of the members to elect a different, if not a better, body of men to represent them on the Council. Better the present abuse than the apathy which has too long been displayed by the majority of the veterinary profession.

AUDI ALTERAM PARTEM.

Dear Sir,—I have read the letters appearing in your journal during the last week or two respecting the shortcomings of the Council. I think it is deeply to be regretted that the language of the respective contributors has not taken a more moderate and less abusive tone. To say that its members have "axes to grind," "take all and give nothing," etc., are accusations that are, in my opinion, both unjust and untruthful. The Council is representative of the profession and the bodies associated with it. The schools are represented, and justly so; the Board of Agriculture and the Army have also their representatives, each to look after the respective interests, in addition to the general welfare of the profession. Then there are the general practitioners—men who give their time and money willingly, and endeavour to carry out their duties with fairness and consideration. Will those who are so ready with their abuse of the Council be a little more constructive in their criticisms, and plainly state where the Council has failed? Not one word has been said on this point. It is so easy to generalise and abuse.

The writers complain that the majority are what is usually termed "silent members." For my part I think this is as well. If all were great talkers little work would be got through; indeed, I have often noticed what a lot of talk centres round a very small point. Again, wherever bodies meet it always has been—and always will be to the end—certain men will lead, be it in the House of Commons or anywhere else. But it by no means follows that the silent men are useless. Frequently the latter are the most useful men in committees—and, after all, the principal work is done there. When the different Chairmen of Committees read their reports to the Council it is only a précis of the conclusions come to, and has probably taken hours to arrive at.

I have, through a long period of years, noted men of the agitating order, who have entered Council to revolutionise everything and everybody, become as silent after their very first meeting as those to whom allusion has so often been made. Council work is not learnt in five minutes—let there be no misunderstanding on that point. It requires an apprenticeship to understand bye-laws. Get your Register out and read through those and the Charters, and see where you stand.

If the profession requires fresh representatives by all means have them—the matter is a simple one. I dare say a goodly number of those now representing us would willingly stand aside if asked to do so. But do drop abuse of men who are actuated by the best of motives, and who have been chosen as representatives by ourselves. Do play a clean game, and not besmirch the characters of honest men who have done their best. The change, if desirable, could surely be brought about by different methods.

FAIRPLAY.

### Sterilisation of Iodoform

"Place 10 gms. of iodoform in a yellow glass bottle of the capacity of 120 c.c., and add to it 60 c.c. of a 1:1000 solution of mercuric chloride. Shake together thoroughly so as to sterilise the iodoform, and add 3 gms. of olive oil, previously sterilised by heat. Again shake up until the iodoform forms a homogeneous mass with the oil. Allow to separate, decant, and reject the aqueous portion, thoroughly draining out the last trace of water, then add 87 gms. of sterile olive oil."

Iodoform may also be sterilised by shaking one part with two parts of 10 per cent. solution of formaldehyde, or it may be treated for three days with a 5 per cent. solution of carbolic acid containing 1 in 2000 of mercuric chloride.—*Pharm. Jnl.*

### Cruelty prosecution at Sheffield— successful appeal.

Henry Cranfield, blacksmith, Oughtibridge, was fined £5 by the Sheffield magistrates, on November 8th last, for cruelly ill-treating a pony belonging to William C. Fairweather, Hill Top, Oughtibridge.

On , at the General Quarter Sessions, for the West Riding of Yorkshire, at Sheffield, before Sir Samuel Roberts, M.P. (presiding), Mr. G. H. Norton, Mr. C. Wright, and Mr. E. Rose, the conviction was successfully appealed against.

Mr. Valentine Ball and Mr. Courtney Sandford were for the respondent, and Mr. T. E. Ellison and Mr. H. R. Bramley, instructed by Mr. J. E. Wing, for appellant.

Mr. Valentine Ball said Fairweather took the pony to be shod at Cranfield's. A twitch was used. The blacksmith struck the pony several times with the hammer and hammer shaft, the pony reared up, fell backwards, and fell down dead.

William C. Fairweather said when the pony pulled its hind foot away the blacksmith struck it five or six times on the ribs, and after the twitch was put on struck it on the head and neck. It reared up, and came down dead.

In reply to Mr. Ellison, witness said the blows were heavy. He wanted compensation for his pony. The prosecution was taken by the Royal Society for the Prevention of Cruelty to Animals.

The cause of death of the pony was rupture of the aorta, said Mr. Herbert Reginald Laycock, M.R.C.V.S. In his opinion the pony dropped dead from fright through the blows administered. The exertion in trying to get out of the way of the blows occasioned the rupture. There were no traces of bruises on the carcass.

Mr. Ellison contended that the whole case had been grossly exaggerated, and that the death of the pony was occasioned by plaintiff's own act in putting on the twitch.

The pony was a very awkward one, and "kicked like a steam engine," said Cranfield. Fairweather put on the twitch, and the pony struggled and died.

After hearing the evidence of Capt. Francis Summers, M.R.C.V.S., and Mr. Stephen Ernest Sampson, M.R.C.V.S.,

The Chairman said they were not satisfied that the pony died absolutely from cruelty. The evidence was conflicting, and the probability was that the pony dropped down dead from fright, not caused directly by cruelty. The conviction would be quashed.

[We are obliged to our unidentified correspondent for this "cutting," but *we much prefer* to have the date, and the name of the paper—both of which are given if page containing the matter is sent intact—postage  $\frac{1}{2}$ d.]

**MARGARINE FROM COAL.**—Prof. George Knox, Principal of the South Wales and Monmouthshire School of Mines, lecturing at the Wigan Mining College recently, stated that during the war margarine had actually been made from coal. Unfortunately, however, like all other fatty bodies derived from coal, the product was of little value as a fat former, but it helped to make bread more palatable. If only they could recover all the by-products formed by its destructive distillation, coal would have three times its present value.

Great Britain has only 2.6 per cent. of the coal reserves of the world, so that it is about time active measures were taken to obviate the enormous waste of coal and its by-products now taking place.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1594.

JANUARY 25, 1919.

VOL. XXXI.

## NOMINATIONS FOR ELECTION TO COUNCIL.

The following nominations have been made. The last day for nomination of candidates is Friday next, 31st inst., and the "foreign" voting papers, to members who are at a distance, will be issued a few days later.

Candidate.	Nominated by
A. LAWSON ...	Messrs. Garnett, Brittlebank
S. STOCKMAN ...	Trigger, Garnett
G. H. GAIGER ...	Stockman, Wilson
O. C. BRADLEY ...	Abson, Sumner
G. P. MALE ...	Banham, Coleman
D. HAMILTON ...	Bradley, Wilson

Of these, the first four are for re-election, and three of them hold positions which make their presence on the Council justifiable—and desirable. Of the two new men, Mr. G. P. Male is best known at this end of England as a capable, up-to-date practitioner, who has steadily upheld the status of the practitioner by both precept and practice, and has put in years of good work in the Royal Counties Society, of which he is this year President; and to whom, with a few other men, belongs the credit of keeping the Society going through the recent troublous years.

Mr. D. Hamilton is less well known, but with two good sponsors we must conclude that he is a worthy candidate.

As in previous years, our columns are open to candidates to state their views at any reasonable length—always remembering that paper is not yet plentiful, and space is therefore still a consideration.

## A DEPARTURE IN EDUCATION.

An experiment has been initiated at the University of Columbia, U.S.A., which, as outlined in a note quoted on page 263, promises to materially assist the selection of men for professional life.

It has for years past been a subject of regret amongst the more thoughtful members of the medical profession that many men who are unsuitable are admitted to the profession on educational qualification—in other words the examination test alone will not indicate the man who will make a skilful and reputable practitioner. That some finer protective network is required is suggested by the passage in the recent report of our Examination Committee which states that applications were received for concessions in the examinations by a B student rejected three times, and a C student rejected five times. It is one of the penalties of poverty that our schools should need to keep such men on their books: but until the Officers of the State understand and acknowledge the value of our work to the nation, and find the means to keep the Colleges in a healthy financial position, we can scarcely hope for improvement. It is a scandal; paralleled by the ignorant neglect of our agriculture as a national asset.

## EQUINE DIGESTIVE DISORDERS.

Comparatively little has been written upon this subject recently. This is not because it has become less important to practitioners than before; for the reverse is the case. The horse is a more important veterinary patient than he was five years ago; and the particular diseases have gained in importance for that general reason and for other special ones. Such prime causative factors of equine digestive troubles as overwork and improper or irregular feeding have been more active during the war. Their results have been manifest in both civil and military practice; but very little has been written upon the subject.

This is all the more regrettable from the fact that, in the years immediately preceding 1914, there was good reason to believe that the study of the subject in England was entering upon a new phase. Clinicians generally were studying the causes and differential diagnoses of these diseases more closely than ever before; post-mortem examinations were more frequent and more careful, and treatment had undergone considerable modifications within the previous decade. Take the common and exceedingly difficult question of the differentiation of the equine colics. The publication by Gofton in 1912 of the first English observations of obstruction of the caecum was one characteristic sign of the times. Another was the increased attention then being paid to displacements, not necessarily considerable or irreducible, of the large colon—a subject which, though some practitioners may still be inclined to regard it as "theoretical" is nevertheless exceedingly practical, and may yet assume the same importance here as it has on the Continent. English clinicians, at that time, were beginning to follow the lead of their Continental brethren with respect to equine digestive disorders, though in many cases they were doing so quite independently. Their work was already showing considerable results, and seemed likely to show more. That hopeful period seems to have terminated for the present; for little has since been published upon the subject.

Yet in the meantime the whole subject has actually gained in importance, as most practitioners know. Old causes of these diseases are still at work, accentuated by war conditions; and some new causes have arisen. Practitioners are daily dealing with all as best they can—and saying nothing of their results. We seem to be on the eve of a temporary revival in horse practice; but as a profession we are hardly going the right way to equip ourselves for it.

## CLINICAL CASES (DOGS.)

The following cases are recorded as illustrating the natural powers of resistance and repair of the tissues in the dog.

*Case I.* A small mongrel fox-terrier bitch was brought in from a farm for treatment, having been trodden on by a cart horse.

On examination, a dirty blood stained mass was seen protruding from the abdominal cavity, in the right inguinal region. This mass was seven inches in length and two and-a-half inches in diameter. At the point of exit it was constricted by the small opening in the abdominal wall to a diameter of three-quarters of an inch. The animal was prostrate, the mucous membrane of the mouth pallid, the pulse weak, and the body surface cold.

The animal was chloroformed, and the protruding tissues, after being cleansed, were found to consist chiefly of a portion of the mesentery, with its vessels engorged, and there was also a small portion of intestine in the upper portion of the mass, in the part nearest to the point of exit from the abdominal cavity.

A silk ligature was applied to the mesentery as near the point of exit as possible, and the stump returned with the loop of intestine to the cavity of the abdomen. The breach in the abdominal muscles was closed with interrupted sutures of Rhea fibre, the opening in the skin, which was slightly enlarged to admit of better drainage, being left patent.

After five days the sutures in the abdominal muscles were removed and the dressing of 1:1000 Chinosol, which had been used throughout, was continued twice daily for another five days, the animal being then returned to the owner. The case gave no further trouble, made a complete recovery, which extended to the writers knowledge up to two years after the operation.

*Case II.* The subject was an Irish terrier, 10 years of age, whose only previous history of having been treated, except for wounds, had been for an attack of Biliary fever, due to infection by *Piroplasma canis*.

When first brought for treatment the history was "he had been dull for several days, and then a couple of days previously a slight swelling had been noticed in the right flank. He was constipated and when given castor or milk vomited."

On examination, the temperature was 103.2 F, pulse hard, tongue furred, and the animal in a depressed condition. A deep seated abscess appeared to be forming in the right flank, about an inch posterior to the middle third of the last rib.

Treatment the first day was confined to giving an enema of Olive oil, and painting the skin over the swelling with Tr. Iodi.

The following morning, as there appeared to be no relief of the symptoms, it was decided to operate. The animal was anaesthetised with chloroform, an incision made through the skin over the swelling and then through the external muscular layer, which exposed a cavity contains a dirty grey fluid with necrotic debris of muscle. On the latter being

removed, a sharp solid body could be felt which, after a slight dissection, was removed with the forceps and proved to be a portion of the scapula of a fowl, a triangular flattened piece of bone  $1\frac{1}{4}$  inches in length which had made its way from the intestine. Owing to the danger of extending the localised peritonitis at the point of exit of this foreign body, the operation was confined to removing necrotic debris, swabbing out the wound with a solution of Lysol, and inserting a gauze plug as a drain.

During the next few days there was an improvement in the animal's condition, liquid food was retained but the faeces were liquid, and only passed in small quantities. On the fifth day after the operation, the site of the operation wound which had commenced to heal, again became swollen, and a further operation resulted in a smaller piece of bone being removed.

After the latter operation there was a rapid improvement in the animal's health. He was kept on a fluid diet for a week and then gradually brought out to his normal diet of boiled rice and fowl (without the bones this time.) During the remaining three-and-a-half years of this animal's life up to the time he was destroyed on account of becoming deaf and blind, there was not any trouble to show that any adhesions that may have formed were interfering with the normal action of the intestine.

J. A. GRIFFITHS, M.R.C.V.S.

Rinderpest Commission, New Langenburg (G.E.A.)

## ABSTRACTS FROM FOREIGN JOURNALS.

ASKARON, A TOXIC CONSTITUENT OF HELMINTHS, ESPECIALLY OF ASCARIDES: ITS BIOLOGICAL ACTION.

Sbimamure Torai and Fujh Hajime have published an article upon this subject (*Boll. Ist. Int. d'Agr.*). From ascaridian mesenteric liquid and from dried and pulverised ascarides (*A. lumbricoides* of man and the pig, and *A. megalocephala*) they have isolated a highly toxic albumose-peptone, for which they propose the name of "Askaron." This substance provokes all the symptoms of intoxication which are observed in ascariasis, and in consequence of injections of the mesenteric liquid or aqueous extract of *Ascaris*. It is fairly well diffused among other helminths. The authors have demonstrated its presence, with identical toxicity, in *Filaria immitis*, *Gastrophilus* larvæ, *Sclerostomum vulgare*, *Oxyuris curvula*, and *Tricocephalus depressiusculus*.

Etheric and alcoholic extracts of dried and pulverised ascarides, even in strong doses, are atoxic; but they have a hæmolytic action. The latter, however, is absent from askaron.

The horse is the most sensitive experimental animal; and next come the guinea-pig, dog, and rabbit. The rat and mouse are refractory.

The principal symptoms of intoxication produced by askaron are difficulty of respiration, dilatation of the peripheral blood-vessels, intensification of the secretions and excretions, nervous disturbances, and depression of the temperature and blood pres-

sure. The post-mortem findings are dilatation of the lungs (in the guinea-pig), hyperæmia and hæmorrhagic exudate in the gastro-enteric tube, endocardium, and internal organs (especially in the lungs), and incomplete coagulation of the blood. The mortal dose of crude askaron per kilogramme of live weight, by intravenous injection, is 0.004 milligrammes for the horse, 0.8 for the guinea-pig, 2.0 for the dog, and 5.0 for the rabbit.

In the horse, ocular instillations of even very dilute solutions of crude askaron always provoke severe lachrymation; this is attributed to the volatile substances of the ascarides. With repeated instillations the reaction always becomes more feeble, but never disappears.

After a first intoxication with askaron, a strong resistance develops very rapidly. Samples of askaron proceeding from different species of helminths are reciprocally protective in equal grades.

Askaron is primarily toxic to a high degree; the serum of the normal horse does not contain antibodies against it. the horse may be actively immunised against a dose of askaron 400 times greater than the lethal one; and this high immunity should be ascribed to cellular resistance.

In the worms themselves, askaron may be regarded as a product of metabolism.—(*La Clinica Veterinaria*.)

#### DERBYSHIRE VETERINARY ASSOCIATION.

The quarterly meeting of the Association was held at Derby, on Tuesday, January 14. The President, Mr. A. Levie, Derby, occupied the chair, and there were also present: Messrs. J. T. Abell, Derby; G. Howe, Buxton; E. Marrison, Bakewell; T. H. L. Duckworth, Ashbourne; J. C. De Ville, Uttoxeter; C. Barnes, Cheadle; and F. T. Prince, Ashbourne, Hon. Secretary.

#### PRESIDENTIAL ADDRESS.

Mr. A. LEVIE.

The President, in his opening address, said he very much appreciated the honour of being elected the first President of the Association. He looked upon the duties as onerous, because they were faced with an important programme from which they hoped good would result, not only to the members individually, but to the profession as a whole. In the period of reconstruction upon which the country was entering, it behoved the veterinary surgeon to look after his own interests and see that he was not left behind in the race for social and economic betterment. Their efforts must be directed to progress through reform, and if they were to attain their ideals and raise the social status of their profession they must take a united stand on all matters in which their interests were challenged or involved. They must in word and in deed act up to their famous motto, "Strengthened by unity." To do this, they must set aside all petty professional jealousies which might exist. They must discuss more freely their professional affairs, interest themselves in public administrative work, secure representation on local bodies, and there voice the claims of the profession to official recognition whenever opportunity occurred. Especially must they be watchful of the medical profession, or at least that branch of it that was devoted to public health. Medical Officers were no friends of the veterinary profession, or they would not allow important offices, in which a veterinary training was essential, to be filled by laymen. In the department of Public Health, doctors endeavoured to thwart the upward movement of the veterinary profession by throwing obstacles in the way. Medical officers must be taught to mind their own business and to understand that veterinary surgeons, with a long College training, were quite capable of dealing with their own affairs without outside interference. Therefore they must see that veterinary appointments under Corporations and County Councils were held by duly qualified veterinary surgeons who would not be required to play second fiddle to the medical officer of health, but who would have full control of their own department. If they were

all united, he was quite satisfied that they could obtain that object. That was the line of progress which the Derbyshire Association intended to follow, and he appealed to the profession as a whole to support them in their endeavour to secure the recognition to which he believed they were entitled.

#### FEES FOR EXAMINATION.

Several members referred to the question of a uniform fee for the examination of horses for soundness, and expressed the view that united action was necessary in their mutual interest.

The following resolution was proposed by Mr. Duckworth, seconded by Mr. Marrison, and carried unanimously: "That the minimum fee for examination as to soundness, with or without a certificate, should be one guinea, and that mileage should be charged extra."

#### PRACTITIONERS' ACCOUNTS.

The PRESIDENT said it would be a good thing if practitioners would notify each other of persons who ran up accounts that they never intended to pay. Some unscrupulous people got into one man's debt and then changed to another veterinary surgeon. He thought a central bureau where information on that point could be obtained would be a very good thing. Practitioners were generally disposed to help the really poor man, whose only horse, on which he depended for his living, needed attention, but that was very different from the case of a man who was well able to pay but who preferred to get into debt.

With regard to the sending out of accounts, it had been the practice of some of them in the past to send them out in detail, whilst others had simply charged a lump sum. He invited members who adopted the latter course to give the meeting the benefit of their experience.

Mr. DUCKWORTH said he now sent out his bills, "To professional attendance from such a date to such a date." "Professional attendance and medicine" was his usual formula, and only once this last year had he been asked for details. He then supplied the details, but without mentioning any prices.

Mr. DEVILLE said his experience was equally satisfactory.

Mr. ABELL said he charged his clients a lump sum and had never had any complaint.

Mr. MARRISON said that except in one or two special cases he had never given details in his accounts for sixteen years.

#### AGRICULTURAL SHOWS AND MEDICINE VENDORS.

Mr. DUCKWORTH raised the question of veterinary surgeons accepting honorary appointments at local agricultural shows where quack medicine vendors were allowed to pitch their stands. He considered it was an insult to ask a veterinary surgeon to give his time at a show at which patent medicines, which undercut the profession, were freely sold.

Other members shared Mr. Duckworth's views, and the suggestion was made that in such cases veterinary surgeons should insist on charging a fee.

Mr. DEVILLE thought it would be difficult to take such a stand in a very small town, where practically all the local exhibitors were one's own clients.

The PRESIDENT said this was a point on which they could only hope to succeed by unity of action. He believed that if veterinary surgeons everywhere were agreed they would carry the day.

On the motion of Mr. Duckworth, seconded by Mr. Howe, the following resolution was unanimously carried: "That at forthcoming shows veterinary surgeons refuse to act in an honorary capacity if medicine vendors are allowed to have stands, and that in such cases a

reasonable fee be charged." It was further resolved to send a copy of this resolution to other Veterinary Associations throughout the country.

*Dates of meetings.* It was agreed that the meetings of the Association be held on the first Tuesday in the months of January, April, July, and October, at the St. James' Hotel, Derby, at three o'clock in the afternoon.

F. T. PRINCE, Hon. Sec.

#### VICTORIA VETERINARY BENEVOLENT FUND.

A meeting of the Council of the Fund was held at 10 Red Lion Square, London, W.C., on Thursday, Jan. 9th., when the following members were in attendance:—Mr. S. H. Slocock, President, in the Chair; Messrs. E. W. Baker, G. A. Banham, T. S. Price, R. C. Trigger, E. A. West, G. H. Wooldridge, J. Willett, and P. J. L. Kelland, Hon. Secretary. Apologies for absence were received from Messrs. Dunstan, Gooch, McIntosh, and Young.

The minutes of the previous meeting were taken as read, and confirmed.

#### HON. SECRETARIES' REPORT.

Since the previous quarterly meeting the following new Subscriptions and Donations have been received:—

#### Collecting Boxes.

E. Whitley Baker	12	6	A. M. Munro	5	15	2
G. A. Banham	10	6	J. H. Kelland		10	0
W. F. Barrett	1	2	F. L. Gooch		10	0
J. L. Cormack	1	10	S. H. Slocock		10	0
J. W. Conchie	1	14	J. & H. Sumner	1	0	0
E. R. Edwards	7	0	J. Willett	1	8	0
F. W. Garnett	10	0	S. M. Woodward		15	0

The total number of new subscribers gained during the year is 66. The total amount received from collect-boxes is £20.

Acting on the instructions of the Council at the October meeting, the President and Treasurer increased the grants in twelve cases, involving a monthly increase in all of £9 4s. 2d. In case 41, a grant of 10/- per month was paid for three months, but a cheque has now been received from the recipient in repayment of the grant made, relief being no longer required.

Following the example set by other Benevolent Societies, the President and Treasurer decided to send out to each recipient on the books a Special Victory Bonus of £1. This was distributed before Christmas, and has been acknowledged in every case by the recipients with much gratitude. It is hoped that the Council will approve the action taken.

On the motion of Mr. Trigger, seconded by Mr. Price, it was resolved: That the report be adopted, and that the action taken by the President and Treasurer be approved.

Mr. WILLETT drew attention to the very gratifying result of the provision of collecting boxes, and expressed the hope that boxes would be taken by a larger number of members.

*Stephenson Bequest.* The Solicitor reported the progress made with the incorporation of the Society, and he was requested to inform the Honorary Secretaries as soon as the incorporation was complete, in order that a special meeting should be called for the purpose of obtaining the necessary signatures to the Memorandum and Articles of Association, and for deciding as to investment of funds.

*Cases for consideration.* No. 7.—Application for grant towards son's outfit. On the proposition of Prof. Wooldridge, seconded by Mr. Price, it was resolved: That a grant of £25 be made in this case, and that the sum of 5/- weekly, previously paid, be withdrawn.

No. 43. On the proposition of Mr. Willett, seconded by Mr. West, it was resolved: That the applicant be informed that the Council cannot see their way to render assistance, in view of the fact that they have many more urgent cases on the books.

No. 42. On the proposition of Mr. West, seconded by Prof. Wooldridge, it was resolved: That the applicant be informed that in view of more urgent calls on the funds, the Council is unable to accede to her request.

P. J. L. KELLAND, } Hon Secs.  
FRED BULLOCK, }

#### The R.A.V.C. Comforts Fund.

Dear Sir,—The Committee, R.A.V.C. Comforts Fund, wishes to convey its grateful thanks to Mr. J. Ewing Johnston, M.B.E., and to Mr. F. W. Brittain for the magnificent cheque of £1000 sent in as a Christmas gift to the Fund.

This is Belfast's splendid reply to an appeal made by Col. R. H. Holmes, C.M.G., D.D.V.S., Ireland, on behalf of the Royal Army Veterinary Corps Comforts Fund.

The Corps can hardly be sufficiently grateful to Mr. Ewing Johnston and Mr. Brittain for the wonderful organisation which has resulted in the production of this large sum.

Substantial financial help has come from many professional men who were already up to the hilt in work—yet they have found both time and energy to produce the very excellent results which have at different times been announced in *The Record*.

It is hoped to continue the Fund until demobilisation is complete.—Yours faithfully,

E. A. BLENKINSOP.

29/7 Bramham Gardens, S.W.

Mrs. Cowan: 20 mufflers, 10 pr. mitts.  
Mrs. Lawrie: 2 pr. gloves, 1 muffler, 1 helmet  
Mrs. Porteous: 1 mufflers. Mrs. Villar: 1 muffler  
Mrs. Harris, St. Alban's Work Party: 22 mufflers, 4 pr. Mitts.  
Mrs. Prichard: 7 mufflers, 1 pr. mitts. [mitts, 1 pr. cuffs  
Mrs. Garnett: 17 mufflers, 20 pr. socks, 2 pr. gloves  
Mrs. Mosley: 1 muffler, 1 pr. gloves  
Mrs. Malcolm Gordon: 13 mufflers, 3 pr. mitts.  
Mrs. Kirby: 4 mufflers. Mrs. Kay Lees: 18 pks. cards  
Mrs. Perry: 12 pks. cards. Mrs. Cockrane: 5 pks. cards  
Mrs. McGowan: 2 pks. cards, 2 games  
Mrs. Blenkinsop: 10 pks. cards

#### GLASGOW VETERINARY COLLEGE.

A Meeting of the Governors of the Glasgow Veterinary College was held within the Secretary's office, 105 Saint Vincent St., Glasgow, on Wednesday, 15th inst., at 3 p.m., Sir Hugh Shaw Stewart, Bart., C.B. in the Chair.

The following appointments to the Board of Governors were reported:—

- (1) By the County Council of Dumbarton—  
Capt. Alan Burns.

- (2) By the County Council of Renfrew—  
Messrs. Matthew Bowie, William Marshall,  
A. A. Hagart Spiers of Elderslie, John  
Stewart, and John Wilkinson.

- (3) By the School Board of Glasgow—  
Mr. Thomas O'Hare, B.L.

- (4) By the Glasgow Agricultural Society—  
Mr. William Strang.

Mr. Hugh Duncan, the Secretary, intimated that the contributions received by him to date to the Sheep Diseases Investigation Fund amounted to £487 5s. 1d., and that Prof. Geiger was assiduously devoting himself to Research Work in connection the matter.

It was further reported that a number of former students had already been demobilised from the Army, and that it was expected there would be a large increase in the number of students in a short time.

### COCCIDIOSIS IN THE RABBIT.

To the Editor of "The Veterinary Record."

Sir,—The letter from Mr. J. B. Buxton which appears in *The Veterinary Record* of the 18th inst., in reply to mine in the previous issue, calls for a short rejoinder.

Mr. Buxton apparently wishes your readers to believe that the statements which he made at the meeting of the Central Veterinary Society conflict only with peculiar views held by myself, and that he has a good defence for what he said if he only cared to make it. That attitude, however, is not consistent with honesty and a knowledge of the subject.

I have not put forward any peculiar or special views concerning coccidiosis in the rabbit, either as regards the life history of the parasite or the lesions which it causes. The mis-statements made by Mr. Buxton related to matters about which there is no difference of opinion among protozoologists and pathologists at the present day.

I am, Sir,  
Ryl. Vet. Coll.,  
21st January.

Your obedient servant,  
J. M'FADYEAN.

### Test for mentally inert at the University of Columbia, U.S.A.

A selective draft system for eliminating the mentally inert from entrance into Columbia University has been decided upon by the University Faculty. Hereafter, psychological tests based on the Binet formula, modified by tests of the American War Department, will be enforced upon all applicants for matriculation, thus providing room for other students who have the intellectual right to a university career.

This experiment is a development of the excellent results obtained by the American Army in applying psychological tests in officers' training schools to determine whether applicants with book learning also had the mental qualities necessary for occupying commanding positions. Prof. Jones, head of the department of admissions to Columbia, explains:

"Examinations will be held as formerly, but in the opinion of the Faculty, many who can comply with the traditional requirements of admission do not make good university material, and such applicants we hope to exclude. It has been found that many students in the preparatory schools could be coached to pass university entrance examinations, but some of them had not the mental capacity for further profitable education. It is better for them and for the University that they should stay out and get into a more suitable environment, where they can make something of themselves."—*The Times*.

### ARMY VETERINARY SERVICE

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Jan. 17.

#### REGULAR FORCES. ROYAL ARMY VETERINARY CORPS

Temp. Capt. E. Armstrong relinquishes his commn. on acct. of ill-health contracted on active service (Jan. 18), and retains the rank of Capt.

#### TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Jan. 18.

Temp. Capt. T. G. Heatley to be actg. Maj. while comdg. a Vety. Hosp. (Dec. 14, 1918).

Jan. 22.

The initials of Lt.-Col. C. B. M. Harris, D.S.O., F.R.C.V.S., are as now described, and not as in *Gazette* of Jan. 4. Capt. J. C. S. Powell relinquishes his commn. on acct. of ill-health contracted on active service (Jan. 23), and retains the rank of Capt.

### Diseased Army Horses.

Mr. Hawk called attention to the fact that a large number of army horses were being brought into the county (Cornwall) carrying with them sundry diseases, including mange of the very worst type and glanders. Precautions had been taken in the county under the direction of the Army Veterinary Department by spraying horses at a very great cost, and it was hoped in that way to prevent the spread of the diseases. But they had no guarantee with regard to "cast" horses, and even if they had, he believed it was admitted they must bring some disease with them. It could therefore be seen the county was in great danger, and, indeed, the country, of the spread of the diseases to home horses. What steps could be taken by the committee? The best sanitary measures should be employed at hostels and other places where horses congregated. He feared a serious outbreak in the county, and they must take time by the forelock.

The Chairman: Someone would be liable for bringing diseased horses into the county. The best thing is to prevent such animals coming in.

Mr. Hawk said that as far as he could ascertain no precautions were taken, but even if they were, and the disease suppressed for a time, the most astute veterinary might be unable to detect it while it was suppressed, and yet it broke out again. So if they had a guarantee, which they had not, it would not guard against the danger they were faced with.

Mr. Banfield said if the disease was properly cured it did not come on again.

Mr. Hawk said they saw these horses marked a, b, c, or d, and those marked "d" were to be destroyed for food. If anything was to be done in Cornwall theirs was the committee to do it.

Mr. A. Cox thought the only step would be to examine horses before they were sold, to treat them if they required treatment, and not to sell them until they were fit. Surely that authority could refuse to allow horses to be sold if a veterinary certified them to be suffering from disease.

It was stated that the committee had no power to prevent diseased animals being sold, and the clerk (Mr. Coward) said the Army authorities sold the horses just as they were, under no guarantee. If anyone was buying a horse he should have it examined by a veterinary before purchase.

Mr. Hawk was empowered to take any suitable steps in the matter, and to act with Mr. Banfield in an expenditure up to £50.

Mr. Cox suggested that the Board of Agriculture should be asked to communicate with the Army

authorities to prevent diseased animals being sent out, but this was not adopted. It was, however, agreed to distribute among farmers and dealers copies of a Board of Agriculture circular dealing with the treatment of disease.—*Western Morning News*, January 16.

#### OBITUARY.

P. WOODROFFE HILL, M.R.C.V.S., St. Leonards.  
Graduated, Lond: May, 1894.

Mr. Hill died at Southend-on-Sea, on January 6th, aged 46.

JAMES CLEVELAND, M.R.C.V.S., Bungay, Suffolk.  
Lond: March, 1874.

Death occurred 18th Jan., at the age of 66.

WILLIAM LITTLE, M.R.C.V.S., Wainfleet, Lincs.  
Edin: April, 1866.

Mr. Little passed away January 12, at 72 years of age

W. R. OWEN WILLIAMS, M.R.C.V.S., G.V.O. Salisbury.  
Rhodesia. L'pool: July, 1910.

Died 16th December, 1918, from pneumonia following Influenza.

Dear Sir,—It is with the greatest regret that I have to advise the death, at the early age of 32, of Mr. W. R. O. Williams, M.R.C.V.S. of the Rhodesia Veterinary Staff.

Mr. Williams died on the 16th inst., from Pneumonia and heart failure resulting from an attack of Spanish Influenza. He was a son of Prof. Owen Williams, Veterinary School, Liverpool University, and a grandson of Principal Williams, New Veterinary College, Edinburgh.

I enclose a cutting from the *Rhodesia Herald* to which it is unnecessary to add except to say that he is a great loss to the profession and to Rhodesia.

Yours faithfully,

Salisbury, G. M. SINCLAIR,  
21st November, 1918. Chief Veterinary Surgeon.

"It will be recalled that Mr. Williams left Salisbury on October 31st for the purpose of inoculating railway employees on the Salisbury-Livingstone section of the B. and M. and Rhodesia Railways and was taken ill at Gwelo. For several days past the news concerning Mr. Williams has been to the effect that he was seriously ill, and doubts were entertained as to his recovery. It was hoped on Friday, that he would have strength to resist the malady, owing to his robust constitution, despite a

message that only the slightest hopes were entertained of his life.

The late Mr. Williams was the District Veterinary Surgeon, Salisbury, having joined the Department of Agriculture in December, 1910. He was a brilliant member of his profession and was exceedingly popular, both among his confreres, and among the farming community; he never spared himself when engaged in the arduous work connected with his office. In Salisbury he was a well-known figure and won the esteem of all who knew him by many kindly acts and sound advice on all matters upon which he was consulted. When the recent influenza epidemic broke out in Salisbury he was among the first to offer his services, and performed yeoman work at the Drill Hall in the first sad days. Afterwards he volunteered to assist in the work undertaken by other devoted citizens at the lazaretto, and in company with the late Mr. Ferguson-Mackeown, he knew no fatigue in his endeavours to alleviate the sufferings of the unfortunate natives stricken with pneumonia. At the end of October, with an improved position at the lazaretto, he willingly accepted this mission to tour the Salisbury-Livingstone section of the railways to inoculate the employees against the dread pneumonia. When he left Salisbury he was not in the best of health, but with his usual bright and hopeful temperament he ignored the signs concerning his own health, being only too ready to suffer himself if he could ensure the health of others. So he reached Gwelo, when he was taken ill and was obliged to enter hospital. He died on Saturday, 16th November. As was said of the late Mr. Mackeown, so it can be said of Mr. Williams, that he laid down his life as the result of unselfish devotion to the natives of Salisbury. With his passing Salisbury is the poorer, but the work he rendered will never be forgotten.

Mr. Williams leaves a widow and two young children to mourn his loss. Mrs. Williams, we understand was called to Gwelo some days previously. We tender to the widow and her little ones, and to the deceased's mother who is in Salisbury, as well as to his relatives generally, our heartfelt sympathy, and express the hope that they will gain some little consolation in their great trouble from the knowledge that he died from the malady contracted during his patient and devoted labours administering to the wants of others.

May he rest in peace.—*The Rhodesia Herald*, Salisbury, Monday, November 18th.

FEBRUARY 1, 1919.

VOL. XXXI.

## TEACHERS AS COUNCILMEN.

From time to time members show a tendency to indulge in general disparagement of its Council; and signs of this vagary have appeared lately. In these outbursts we nearly always find strong exception taken to the "over representation" of the schools upon the Council, accompanied by much derogatory criticism of the teacher-legislator. This sort of thing has never yet succeeded in removing the school element from the Council and it will not be to the benefit of the profession if it ever does.

Even were it true—which it certainly is not—that teachers on the Council care for nothing beyond school and examination questions, they would still be indispensable. Matters which profoundly affect the future of the profession are quite as important as anything concerning its present; and the most aggressively "energetic" practitioner can hardly claim that he and his kind are so well fitted to deal with them as schoolmen. Again, the interests of different schools occasionally clash; and it is therefore desirable that each should have at least one representative. These reasons alone render a good school representation imperative; and schoolmen are of value to the Council on quite other grounds.

Supposing that a teacher take a broad view of his responsibilities on the Council and a genuine interest in all branches of veterinary activity, what chance has he of estimating the necessities of the profession? His detractors say "He knows nothing about practitioners and their needs"; but who has greater opportunities of obtaining such knowledge than he? He works in a large city, where he may meet many more veterinary surgeons than are to be met in any country district. Often his work—especially if he be a pathologist or a clinician, brings him into contact with veterinarians much farther afield. Often, also, he keeps in touch with many of his old students; and this in time greatly extends his professional acquaintance. The truth is that hardly any man is so well able to gain a wide and intimate knowledge of the conditions and requirements of the profession as a teacher, especially if in a large school. Compared with his opportunities, those possessed by the great majority of practitioners are insignificant. Add to this the fact that teachers are usually men of more than average natural ability; and it is easy to understand their potency in the Council chamber.

Even those who concern themselves only with their special subjects may do useful work in a restricted but important field. Those who think more broadly—and most do, are among the most valuable men on the Council.

## THE NOMINATIONS.

On page 269 is given the list of nominations to date, which includes the names of three fresh candidates—Messrs. J. Hill, W. Logan, J. Willett—all of whom may be classed as general practitioners, and each best known in his own locality. Both Capt. Hill and Major Logan are at present in khaki, but both hope to be at home again by the time of the election or very shortly after.

## A NOTE ON PIROPLASMOSIS OF THE DONKEY.

Piroplasmosis of the donkey has been recorded as a disease which occurs in various parts of the world. In German East Africa it was recorded by "Schellhase," in 1914 (i).

My experience of the disease has been confined to outbreaks dealt with in the North Nyasa district of Nyasaland and in the Neu Langenburg and Iringa districts of German East Africa.

The disease appears to affect more severely the white "Zanzibar" donkey (the local descendant of Muscat donkey) and crosses of this breed with the native grey donkey. The latter breed shows a high degree of natural resistance, or at least a greater power of natural resistance, the immunity being acquired after a natural infection. This resistance is probably due to the breed being more hardy in every way and better able to withstand the rough conditions of both food and climate met with in this country.

In its most common form the disease runs a chronic course, and parasites are not plentiful in the peripheral blood.

The parasites vary considerably in shape—amoeboid, round, ring, and match-like forms being noted at different times during the course of an acute attack. Pear-shape parasites were rare. Occasionally parasites were seen in pairs, these being either leaf-shaped or match-like forms. In several cases, where the parasites were joined at the extremity away from nucleus, a small granule of chromatin was seen at the point of junction.

The nucleus of the parasite, which is usually towards the periphery in the amoeboid, round, and ring forms is in these cases much smaller than in the pear and match-like varieties of parasite, where it consists of a darkly stained, irregularly rounded mass at one end of the parasite. In all the forms mentioned above, the cytoplasm has a reticulate structure.

No cross forms have been noted in any of the smears taken during the course of any of the above.

mentioned outbreaks. In three cases of acute infection free parasites were seen in the plasma, these being amoeboid and round forms.

The number of parasites varies daily in smears taken in the peripheral blood, and often, even during the course of an acute attack, they may be absent. The heaviest infection noted was 4 p.c., this is, however, exceptionally high. The extent of the infection has no relation to the gravity of the symptoms. In the chronic cases the parasites are often difficult to find, there being, perhaps, not more than half a dozen in a smear.

The smaller round forms of the parasite have the appearance of cocci, it being difficult to differentiate the nucleus from the cytoplasm. These forms are almost invariably placed towards the periphery of the blood corpuscles.

In a number of cases the match-like forms with the darkly stained rounded nucleus at one end, were seen in various stages of longitudinal division, there being a portion of the nucleus in each segment. A common variation of the match-like form is a parasite whose cytoplasm is splaved out in a fan-like manner from the nucleus. A few curved rod-like forms, that have been observed applied to the periphery of the corpuscle, also appear to be a variation of the match-like form.

In one lot of eleven donkeys—one jack and ten females, eight were found to be suffering from the disease and had parasites in the peripheral blood. All these animals were very emaciated, and one died from a secondary infection which resulted in death from pyæmia.

In another lot of eighty odd animals, a mixed troop of breeding animals and their off-spring, up to two and three years olds, the disease in combination with cyclostome infection caused a mortality of 25 p.c. during the course of an observed period of two years. This outbreak was in a low-lying district near the shores of Lake Nyasa, where the greater part of the grazing area was marshy for six months of the year.

Clinically the infected animals, in the chronic form of the disease, show the symptoms of anæmia. The animal is dull, and loses all interest in its surroundings, the mucous membranes are pale, and there is gradual emaciation with progressive weakness. There is no febrile reaction; a high temperature in this form of the disease usually indicates some secondary disease.

During an acute attack the mucous membranes may be at first slightly icteric, later petechiæ become visible, and there is always a rise of temperature to 104 or 105° F. with a quickened pulse. The common complication is broncho-pneumonia, but others, such as pyæmia or septicæmia may follow minor injuries; and pregnant animals often abort.

Piroplasmosis of itself appears rarely to be an actual cause of death, but may reduce the victim's power of resistance to such an extent that it succumbs to any secondary infection.

The period of convalescence is always very prolonged in cases that have once become emaciated, and a great deal of attention to feeding and general hygiene is necessary if the animal is to have a fair

chance to regain its former health. Many animals remain in poor condition, and one is unable to detect any other sign of ill-health. In such cases parasites may be found in the blood but not constantly, and when present there are so few that they are not easily found.

The best results in treatment have been obtained by moving the animals to fresh grazing areas, preferably to another district. Tick infection is, however, the main point to consider in the prevention of the disease, and this can be dealt with by attention to grooming and the application of dressings by hand. A number of the above-mentioned cases were treated by intravenous injections of "Trypanblau"—a 2 p.c. solution in normal saline, without any apparent beneficial result, in doses up to 60 c.c.

J. A. GRIFFITHS.

*Reference.*—(i) Schellhase, W., "Ein Beitrag zur Kenntnis der Piroplasmosi der Schafe und Esel." Reitsch, "Infectionskrank, parasit, Krank u. Hyg. d. Haust," 1914, Feb., Vol. 15, No. 1 (Extracts by "Tropical Vety. Bulletin," June, 1914).

#### A PLEA FOR THE RE-INTRODUCTION OF THE TUBERCULOSIS ORDER.

To those who are interested in the prevention of consumption or tuberculosis, an earnest desire is expressed that they will use all their powers to impress on those in authority, and particularly to approach their respective Members of Parliament of this Order as a by no means negligible effort in the prevention of the disease in mankind, and a step in the prevention of its spread among dairy cattle.

Dr. Noel Badsworth, at the National Federation of Employees Approved Societies, spoke of the prevalence of tuberculosis, stating that more than any other form of illness this disease took its toll of workers in the prime of life. Some idea of the extent of the tuberculosis problem was conveyed by the fact that every year 60,000 deaths occurred from this disease, a number equal to the whole population of Oxford. At this moment there were computed to be a quarter of a million consumptives in the country, the larger proportion of whom were to be found among the working classes. Among the contributory causes of tuberculosis were malnutrition, sweated labour, impure milk, bad housing, overcrowding, and ill-ventilated workshops and workrooms.

Again, Dr. Mitchell, of Edinburgh, cites 72 consecutive cases of tubercular cervical glands in children, and of these 65 (90 p.c.) the organism isolated was of bovine origin, and in 7 (10 p.c.) the human tuberculosis bacillus. In all the cases of bovine tuberculosis the children were fed upon unsterilised cows' milk.

Dr. W. Savage, County M.O.H., Somerset, says that at least 10 p.c. of the market milk contains active, virulent tuberculosis, and that the percentage of tuberculosis in children due to milk is 20 p.c.

This serious condition of affairs is quite com-

prehensible when one reads in the report of the Chief Veterinary Officer of the Board of Agriculture for the year 1914, that from 1st May, 1913, to 30th June, 1914, the returns show 5599 cases in England and Wales of tuberculosis with emaciation in all: this large number of wasters is a great loss to the agriculturists, and, of course, to the State.

A further 1072 cases were diagnosed in life to be giving tubercle-infected milk. On post-mortem examination tuberculosis of the udder was found in 1000 cases. After a period of four and a half years there must again be a number of animals that are daily giving off tubercle bacilli in their milk, infecting a certain proportion of children, whose chief article of diet is cows' milk, and every endeavour should be made to place this food above suspicion.

St. Albans.

G. ELMES, F.R.C.V.S.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### PSEUDO-TUBERCULOSIS OF THE PIG (CASEOUS ADENITIS) AND VISCERAL PSEUDO-TUBERCLES.

Caseous glandular lesions in the form of nodules or more rarely of visceral tubercles, which it is difficult to distinguish from tuberculosis, are frequently found in the pig. Chaussée, in *La Revue de Médecine Vétérinaire* of last year, published the following account of these conditions.

The author relates five cases of this nature, in which inoculation into guinea-pigs proved that the lesions were not bacillary, while the naked-eye examination could give no certainty on the point. These observations enabled him to gain a more exact knowledge of the differential naked-eye characters of the two classes of lesions.

One of these five observations is here given. A pig of fifteen months old, in excellent condition, had both the maxillary glands very slightly hypertrophied. In each of these glands, some fifty caseous points were found. They were hard, had no fibrous envelopes, were of a yellowish cream colour and from one to seven millimetres in thickness. The intermediary glandular tissue was grey, clearly distinct from the lesions, in full vitality, and apparently normal. There were no other visceral lesions. When one of the "pseudo-tubercles" was crushed and microscopically examined, no tubercle bacilli were discovered. The inoculation of guinea pigs confirmed the non-tubercular nature of the condition.

This example and the other cases reported by the author show that nodular caseous non-tubercular lesions of the lymphatic glands exist fairly frequently in the pig. Their differentiation from tuberculosis is not always easy, and is based upon the following characters.

The non tubercular nodules are not regularly spherical, and have no fibrous envelope. Their caseation is complete and uniform, dry, and with calcification. Their colour is that of gum, or greenish.

In the lesions due to Koch's bacillus the nodular

form is rare in the glands of the pig. Glandular tuberculosis is generally of the hypertrophic type, with complete or incomplete degeneration in the form of masses extended over the whole of the major part of the gland. If these tuberculous lesions are of some months standing, the viscera are usually affected by generalisation; while in "pseudo-tuberculosis" they are generally intact. In one of the author's cases of "pseudo-tuberculosis," however, tubercles were found in the lung and the liver; but these were much harder and more calcified than lesions due to the tubercle bacillus. In cases in which tuberculosis and "pseudo-tuberculosis" co-exist the double diagnosis may be difficult; but to recognise the presence of tuberculosis is sufficient.

The lesions of this "pseudo-tuberculosis" are easy to distinguish from parasitic tubercles of the liver—echinococci, and cysticerci.

Not having been able to make the necessary cultivations and inoculation, the author has not investigated the cause of this porcine "pseudo-tuberculosis." He regards the lesions as probably caseous sequestra, due to a previous benign infection of the digestive apparatus. His sole object in publishing his article is to show that it is necessary in practice to know that these lesions exist, and to distinguish them from tuberculosis due to Koch's bacillus.—(*Revista de Higiene y Sanidad Pecuarias*).

##### FIBROMA OF THE TESTICLE IN DOMESTIC ANIMALS.

R. Galli, in *Il Nuovo Ercolani* of 1913, published an article on this subject which is of some interest from the great rarity of fibromata of the testicle in animals, and from the fact that it records three characteristic cases.

The fibromata are benign tumours. They vary in size from that of a pea to a man's fist, and present a small lobulated surface. They are movable and hard; and sometimes they are not uniform. Sections show a shining aspect, a compact texture, a white or yellowish colour, and a periphery which is rounded or has more or less pronounced excrescences. There may be calcified or ossified zones in which the sectioning knife encounters great resistance. On account of the compression caused by these tumours, the tissues constituting the scrotal diverticula tend to excoriation and ulceration. Fibromata grow slowly, and attain a great size. They sometimes undergo sarcomatous transformation, and may then grow rapidly.

Of the author's three cases, the first was in an old ass, the second in a young ass, and the third in an old horse. Very clear and demonstrative microscopic preparations were obtained by staining sections by Van Geissen's method. In all the cases, the typical texture of the fibroma was observed.—(*Revista de Higiene y Sanidad Pecuarias*).

BROAD—NORWOOD. On Tuesday, January 14th, at the Conisbrough Parish Church, Dorothy Mary Norwood, elder daughter of Mr. W. Norwood, M.R.C.V.S., and Mrs. Norwood, of High Street, Conisbrough, was married to Capt. Gerald Herbert Broad, M.R.C.V.S., R.A.V.C., elder son of Mr. Alfred Broad, F.R.C.V.S., and Mrs. Broad, of St. John's Wood, London.

## Royal College of Veterinary Surgeons.

### SPECIAL MEETING OF COUNCIL.

A Special Meeting of Council was held at 10 Red Lion Square, London, W.C. 1, on Friday, January 24th, when the following members were present:—Messrs. G. A. Banham, W. F. Barrett; Sir John M'Fadyean; Messrs. J. McKinna, T. S. Price; Prof. E. S. Shave; Mr. S. H. Slocock.

In the absence of the President, Mr. J. McKinna, Vice-President, was appointed to the Chair.

The minutes of the previous meeting having been published, were taken as read, and confirmed.

Letters of apology for absence were received from Messrs. F. W. Garnett, W. J. Mulvey, Abson, Bradley, Gaiger, Lawson, Packman, Thomson, and Wilson.

#### BYE-LAWS.

On the motion of Mr. Barrett, seconded by Sir John M'Fadyean, it was resolved: That the following additions to Bye-law 61, passed at the Special Meeting of Council on the 10th January, be confirmed:

After the first clause to add the words, "together with a copy of his birth certificate."

"In any special circumstances arising in connection with the war, exemptions or other concessions may be granted by the Council on the recommendation of the Examination Committee to any person who has served in His Majesty's Forces since the 3rd day of August, 1914."

On the proposition of Mr. Barrett, seconded by Prof. Shave, it was resolved: That the following alteration to Bye-law 62a, passed at the Special Meeting of Council held on January 10th, be confirmed:

(1) A student who has obtained a degree in Arts, Science, or Medicine, or a degree or diploma in Agriculture granted by a University situate within the United Kingdom, or by any other body whose degree or diploma in Agriculture is approved for the time being by the Council, on the recommendation of the Examination Committee, or the Diploma of Licentiate of one of the Royal Colleges of Surgeons, or of one of the Royal Colleges of Physicians, and who in procuring such degree or diploma passed an examination in Chemistry and also in Biology, Zoology, or Botany, shall be exempted from the A or first professional examination, and the bye-laws and regulations in respect thereof, and shall be entitled in all respects to the rights and privileges which the passing of such examination ordinarily confers, provided always that such student so exempted shall be examined in the whole subject of Anatomy in the Class B examination.

(2) A student possessing a degree or diploma of a like import or denomination to one of those enumerated in paragraph (1) hereof, but granted by a University or other examining or licensing authority other than those mentioned in paragraph (1) shall, if the Council declare its sufficiency for exemption, thereupon become entitled in all respects to such exemptions, rights and privileges as are defined in paragraph (1) of this bye-law."

On the motion of Mr. Barrett, seconded by Mr. Price, it was resolved: That the Seal of the College be attached to the above alterations to Bye-laws.

#### REPORT OF EXAMINATION COMMITTEE.

The following report of the Examination Committee held earlier in the day was received and adopted:—

*Chairman.* In the absence of the Chairman, Mr. Slocock was appointed to the Chair.

The minutes of the previous meeting having been approved by the Council, were taken as read, and confirmed.

*Preliminary Examinations.* The following applications for exemptions were received:—

1757. H. DAVIES. Private, Agricultural Coy., 2 years' service. College of Preceptors Junior, Sept., 1915—English, Maths., Welsh; June, 1916—Geography, Latin.

1768. W. H. W. BAIRD. Lieutenant, 2½ years' service, Scottish Leaving Certificate (except Latin). Testimonial from Headmaster.

1769. E. J. MULLANE. Pilot, R.A.F., 1½ years' service. Testimonial from Headmaster.

1770. J. R. MORISON. Sergt. A.O.F., 1½ years' service. Mentioned in Orders. Discharged unfit. Testimonial from Headmaster.

1772. E. E. SCOTT. Lieut. (Hon.) R.A.V.C., 4 years' service. Testimonials from Col. Rainey, Capt. Metton, and Headmaster.

1773. G. FRAZER. Private, 2½ years' service. Scotch Educ. Dept. Intermediate (English, Maths., French, Science, Drawing). Testimonial from Headmaster.

1774. E. HAZELTON. Trooper, 5th Reserve Cavalry, 2½ years' service.

1778. D. J. ANTHONY. Lieut. Royal Welsh Fusiliers, 3 years' service.

1779. O. C. ROGERS. Bombardier, R.G.A., 3½ years' service.

It was resolved to recommend: That the applications be acceded to; but that in cases 1774, 1778, 1779, the exemption be conditional upon the production of a satisfactory testimonial as to general education.

#### Special Cases.

1776. R. M. C. GUNN. Staff Farrier Sergt. R.A.S.C., 3 years' service. B.Sc. Agriculture (Sydney), applies for exemption from Prelim. and part of First years' course.

1777. A. F. FLOOD. Sergt. A.A.V.C., 4 years' service. Diploma in Agriculture, Dookie Agric. Coll., Australia. Testimonial from Headmaster of Westminster City School. Applies for exemption from Prelim. and also from part of First year's course.

It was resolved to recommend: That Mr. R. M. C. Gomm and Mr. A. F. Flood be exempted from the Preliminary examination, and also from the first professional examination, on the understanding that the whole subject of Anatomy be taken at the Class B examination.

#### Applications from demobilised Veterinary Students.

A. HOUSTON. Class B student. Passed A Dec., 1916, without Anatomy. Applies to take Class B in July, 1919, together with Junior Anatomy.

E. D. SEWELL. Lieut. W. Yorks Regt., 4½ years' service. Failed D for fourth time, Dec., 1908. Applies to be allowed to return and take D examination in July, 1919.

A. A. EVANS. Class C student. Applies to take C, July, 1919.

The above applications were acceded to.

*Class B Students.* Applications were received from several students in Class B, who had been recently demobilised, for permission to take the Class B examination in July, 1919.

It was resolved to recommend: That the applications be acceded to.

*Women Students.* An application was submitted from Miss E. G. Knight (Diploma in Agriculture, Reading), for admission to the examinations for the Diploma of M.R.C.V.S.

It was resolved: That the Secretary be instructed to inform the applicant that the College does not possess the power to admit women to the examinations for the diploma of Membership.

**Colonial Graduate.** An application was received from Capt. J. B. Leitch, for exemption from Classes A, B and C, and to be admitted to the Final examination after attendance for one session at an affiliated Veterinary College. Capt. Leitch holds a Diploma of Bachelor in Veterinary Science of the University of Melbourne, and served as Veterinary Officer in the South African War, 1900-1902, and again in the European War, 1915-19.

It was resolved to recommend: That the application be acceded to.

#### PARLIAMENTARY BILLS.

The Secretary was authorised to enter into a contract with Messrs. Wyman and Son for a supply of all public Bills submitted to Parliament at an annual cost of £4 10s., and also to make arrangements with Messrs. Sherwood for the inspection of all private Bills, and the report to this College of any matters of interest to the profession.

A vote of thanks was accorded to the Vice President, and the meeting terminated.

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

(In each case the amount subscribed is £1 1s., except where otherwise indicated).

W. Ackroyd, Halifax (£1)	C. St. J. F. Macartney,
N. Almond, Kingston-on-Thames	Capt. R.A.V.C.
W. Ascott, Major R.A.V.C.	F. Marks, Capt. R.A.V.C.
R. M. Bamford, C'n R.A.V.C.	R. Mason, Helmsley
J. Barr, Acle, nr. Norwich	H. Morphew, Loxwood
P. G. Bond, Plymouth	H. J. Parkin, East Ham
W. H. Bloye, Plymouth	J. G. Parr, Leicester
M. Bray, King's Lynn	J. Paton, Stevenage
N. Brear, Capt. R.A.V.C.	W. Pauer, Blackwater
W. Brown, Aberdeen	E. M. Perry, Lt-Col R.A.V.C.
H. Buckingham, Norwich	H. Pollard, Wakefield
J. Clarkson, Garforth	J. W. Froctor, C'n R.A.V.C.
W. A. Clifford, St. Leonards-on-Sea	W. D. Rees, Trealan
R. Cockburn, Eastwood, Notts.	H. A. Reid, Lt-Col R.A.V.C.
A. Cornish Bowden, Beckenham	T. O. Richardson, Tarporly
W. R. Davis, Enfield, N.	H. K. Roberts, C'n R.A.V.C.
H. J. Dawes, W. Bromw'h	E. A. Rucker, Esher
G. R. Dudgeon, Sunderland	G. C. Sharpe, M.C., Capt. R.A.V.C.
J. Dunstan, Liskeard	C. W. B. Sikes, Maj. R.A.V.C.
Prof. S. H. Gaiger, Glas.	S. L. Slocock, M.C., Capt. R.A.V.C.
G. H. Golding, Eastbourne	E. T. Stanley, London, S.E.
W. Hill, Capt. R.A.V.C.	H. P. Standley, Norwich
J. T. Holmes, Bourne	J. W. Sugden, Southmins'r
F. Kerr, Dublin	P. Vincent, Romford
C. J. R. Lawrence, Capt. R.A.V.C.	H. H. Whitlamsmith, London, S.E.
G. Lockwood, Peterboro'	A. E. Willett, Capt. R.A.V.C.
	W. Woods, Wigan
	W. R. Wright, Sidmouth
	J. B. Young, Braintree

56 13 0

Previously acknowledged 467 3 0

£523 16 0

An Army Council instruction just issued states that the landing of dogs in Ireland from Great Britain and the Channel Islands has been totally prohibited until further notice.

#### NOMINATIONS FOR ELECTION TO COUNCIL, JUNE, 1919.

##### Eight Vacancies.

Candidates.	Proposers.
BRADLEY, O. C., Edinburgh	J. Abson, H. Sumner
GAIGER, S. H., Glasgow	S. Stockman, P. Wilson
HAMILTON, D., Hamilton	O. C. Bradley, P. Wilson
HILL, J., Llanelly	D. G. Davies, J. F. Rees
LAWSON, A., Manch'r	F. W. Garnett, J. W. Brittlebank
LOGAN, W., Inverness	R. H. Stordy, L. L. Dixson
MALE, G. P., Reading	G. A. Banham, J. C. Coleman
STOCKMAN, S., London	F. W. Garnett, R. C. Trigger
WHARAM, S., Leeds	S. E. Sampson, J. Clarkson
WILLETT, J., London	J. T. Share-Jones, H. Sumner

#### VICTORIA VETERINARY BENEVOLENT FUND

A special meeting of the Council of the Fund was held at 10 Red Lion Square, London, W.C., on Friday, 24th January, 1919, when the following members were present:—Mr. S. H. Slocock, President, in the Chair, Messrs G. A. Banham, W. F. Barrett, F. L. Gooch, T. S. Price, Sir J. M'Fadyean, Prof. G. H. Wooldridge, Mr. W. Jackson Young, Mr. G. Thatcher, Solicitor, and Messrs P. J. L. Kelland, and F. Bullock, Honorary Secretaries.

The minutes of the previous meeting were read and confirmed.

Apologies for absence were received from D. Bradley, Mr. H. J. Dawes, Mr. E. A. West.

**Incorporation.** The Solicitor reported that the Board of Trade had signified that no objection would be raised to the incorporation of the Fund, with the omission of the word "Limited" from the title. It was thereupon agreed that all members present should sign the Memorandum and Articles of Association, and this was done, the signatures being witnessed by the Solicitor.

The Solicitor reported that the Executors of the late Dr. Stephenson had decided to take the opinion of the court whether the Armstrong College is entitled to participate in the residue of the estate, and that they had asked that the Fund should be appointed to watch the interests of the other residuary legatees (including itself), the costs to come out of the residuary estate.

On the proposition of Mr. Barrett, seconded by Sir J. M'Fadyean, it was resolved that full authority be given to Mr. Thatcher to act for the Fund in the matter, with instructions to consult Counsel if necessary, it being understood that the litigation involved no expense to the Benevolent Fund.

**Investment of Funds.** On the proposition of Mr. Price, seconded by Mr. Young, it was resolved that the whole of the money received in respect of the Stephenson Bequest be invested in 5% War Loan, 1929-47.

**Office Equipment.** On the proposition of Mr. Barrett, seconded by Mr. Banham, it was resolved that a Card Index be purchased at a cost not to exceed seven guineas. Authority was also given to obtain a Roll-top Desk at a cost not to exceed ten guineas.

A lady of Godstone, Surrey, has recovered her wedding ring which disappeared five or six years ago while she was feeding a calf. It was thought the animal had swallowed the ring, and, as it could not be found, the calf became known as "The Golden Cow." A few days ago the cow was purchased by an Oxted butcher, who remembering the lost ring, made a search, and discovered it embedded in an internal organ.—*Daily Telegraph*, January 30th.

**The R.A.V.C. Comforts Fund.**

Dear Sir,—The Committee, R.A.V.C. Comforts Fund once more ask you to be good enough to publish the enclosed list of subscriptions to the Fund.

The total collection of £132 15s. 6d. is entirely due to Lt.-Col. J. W. Brittlebank, C.M.G., who has found time to raise this very satisfactory and substantial sum during the past few months in the Western Command, and the thanks of the Corps are due to him and to all those who have so kindly and helpfully responded to his appeal.—Yours faithfully,

E. A. BLENKINSOP.

29/7 Bramham Gardens, S.W.  
27th January.

Collected by Lt.-Col. J. W. Brittlebank, C.M.G., D.D.V.S.,  
Western Command, Chester.

Jan. 23.

Capt. J. F. D. Tutt relinquishes his commn. on acct. of ill-health (Jan. 24), and retains the rank of Capt.

## OBITUARY.

WILLIAM STANLEY CARLESS, M.R.C.V.S., The Butts, Worcester, Capt. R.A.V.C.

Graduated, Lond : April, 1878.

Capt. Carless' death occurred suddenly at Sheringham, whilst on active service, on Dec. 18, 1918, aged 61.

G. C. TAYLOR, M.R.C.V.S., Nottingham, Lieut. R.A.V.C.  
Lond : July, 1916.

Death resulted from wounds, 6th October, 1918.

## The late Mr. Harvey du Cros.

The death has taken place suddenly from heart failure of Mr. Harvey du Cros, M.P. for Hastings 1906-8, who took a prominent part in the early development of the pneumatic tyre industry. Born in 1846, the son of Edouard Pierre du Cros, of County Kildare, he came of an old Huguenot family which, having been driven from France settled in Ireland. It was in 1888 that Mr. J. B. Dunlop, a Belfast veterinary surgeon, reinvented Thomson's forgotten tyre. At that period cycling was exceedingly popular in Ireland, and among its keenest followers in Dublin were Mr. Harvey du Cros and his six sons, who had for years been conspicuously identified with sports and athletics. They were among the first to recognise the merits of the Dunlop tyre, and Mr. Harvey du Cros formed a company in Dublin in 1889, with a capital of £15,010, to carry on the manufacture. In that year his son, Mr. (now Sir) Arthur du Cros, was not allowed to ride a pneumatic-tyred safety bicycle in the race for the Surrey Cup at the Oval, but in the following year he and a party of Irish racing amateurs carried all before them on the English tracks. There was an immediate demand for the new tyres, but the discovery of the existence of the 1846 Thomson patent led to long litigation. The acquisition by the company of the Welch and Bartlett patents overcame many difficulties and the business proved so successful that in 1896 it was sold for £3,000,000 to a company of which Mr. Arthur du Cros became managing director and his father chairman. Mr. du Cros was elected in 1906 as Conservative member for Hastings, and sat till 1908, when he was succeeded by his son Arthur.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, Jan. 27, 1919

NOTE.—The figures for the Current Year are approximate only.

\* As diseased or Exposed to Infection

## Inquiry on Anthrax.

The work of the Departmental Committee on Anthrax is being extended to an inquiry into the subject of horse hair and anthrax. They have been instructed to make experiments in disinfecting main and tail hair. The Secretary of the Committee, Mr. A. E. Duckering, with Dr. Eurich and Mr. Wm. Mackinder have been appointed a sub-committee to conduct the experiments and to report to the Committee. The purpose of the Committee will be to discover whether the process of disinfection can be applied mechanically and on commercial lines. Certain firms in the Bradford district are to be approached with the view to their giving permission for the carrying out of the experiments.

According to a report presented to the Committee observation extending over a period of nine months showed that 19 cases of anthrax were due to infection by horse hair, and these were not the whole of the cases arising out of the manipulation of this material. The chief place of origin of anthrax-infected horse hair is China, where there appears to be no attempt at disinfection—*Bradford Daily Argus*.

## Parasitic Mange Prosecution.

At Bow Street Police Court on 29th inst, Frederick Byles, of Plough Yard, Curtain Road, Shoreditch, was ordered to pay fines and costs amounting to £34 for failing to notify the police that he had in his possession a horse suffering from parasitic mange, for causing it to be driven on a public highway, and for causing it to be worked while in an unfit state.

Sir Stewart Stockman, Chief Veterinary Officer to the Board of Agriculture, says:—"Horse owners ought to treat their horses for the prevention and cure of external parasitism as farmers treat their sheep, and do it of their own accord. They should feel it a disgrace to their horsemanship to have parasitized horses."

Original articles and reports should be written on one side of the paper only and authenticated by the names and addresses of writers, not necessarily for publication.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1596.

FEBRUARY 8, 1919.

VOL. XXXI.

## CONTAGIOUS DISEASE.

In last week's issue a plea was advanced by Mr. G. Elmes for the re-introduction of the Tuberculosis Order. Doubtless this is urgently needed; but whether it is practicable is a more open question. Just now the whole island is grievously undermanned with veterinary surgeons, especially in country districts. In addition, veterinary responsibilities are increasing, and will continue to increase for some time.

We know that a considerable rise in equine contagious disease in consequence of demobilisation is practically certain. That alone may overstrain an already hard-worked profession. Moreover, rabies and foot-and-mouth disease are threatening us daily; and at any time may become widely dispersed. Foot-and-mouth disease in particular might find too few veterinary surgeons in the country to deal with it effectively.

No doubt the Board will re-impose the Tuberculosis Order the moment they believe it can be satisfactorily worked. We have never been threatened with such an amount and variety of contagious disease; and just now we are certainly numerically insufficient to deal with its possibilities. The conditions of the country as a whole and its veterinary resources are probably well understood at the Board; and we may expect energetic action to be taken as soon as possible. There is an immense amount of work waiting to be done against tuberculosis and several other diseases; but it is doubtful whether much more than we are doing already can be attempted until the veterinary forces of the Kingdom are brought back into line for civil work.

## THE NOMINATIONS.

Since the list appeared in our pages last week, the names of two fresh candidates, and of two others for re-election have been added, so that there are now fourteen candidates for eight vacancies. Of the two new men, the best known probably is Prof. Craig, of Dublin. As a skilled anatomist he is known throughout the profession, and for years past he has taken an active part in the large and influential association, the V.M.A. of Ireland, which includes the leading practitioners of Dublin and neighbouring counties. Mr. J. B. Tutt is a practitioner of standing who is well-known in the South of England, and has frequently given his support as a practitioner in questions of professional interest.

The list to date will be found on another page.

## THE BIOLOGICAL CYCLE OF THE ASCARIS LUMBRICOIDES AND ALLIED FORMS.

B. H. Ramson and W. D. Foster have published an article upon this subject (*Bull. Ist. Inst. d'Agr.*). The biological cycle of the *A. lumbricoides*, the common intestinal round-worm of man, and of *A. suum* or *A. suilla*, very common in the intestine of the pig, has recently been studied by F. H. Stewart of the Indian Medical Service. Despite their different names, these worms are the same parasite, or else are so closely alike that they cannot be distinguished morphologically. The general opinion is that the infection of man or of the pig with *Ascaris* results from ingestion of the eggs of the parasite, but Stewart's researches led him to the conclusion that it is necessary that the eggs should first be ingested by rats or mice, that in these hosts the embryos issue from the eggs, and undergo some migrations and transformations inherent to their development, till, passing into the faeces or saliva of the mice or rats, they contaminate fodder or other material eventually ingested by man or by the pig, which constitute the final hosts. Ramson and Foster have reviewed the repeated experiments of Stewart, and from them, from those of other workers, and from their own, they reach the following conclusions:—

The development of *A. lumbricoides* and forms closely related to it is direct, and does not necessitate an intermediate host. The eggs, when ingested, open in the gastro-intestinal tube; the embryos, however, do not at once take up a residence in the intestine, but migrate to various other organs, among which are the liver, spleen, and lungs. In the case of the *ascaris* of the pig, the migratory larvæ may be found in the lungs within a week, and meanwhile have undergone considerable development and growth. From the lungs the larvæ migrate into the trachea, and thence into the œsophagus by way of the pharynx. This migration into the trachea may be verified in pigs, as also in artificially infected mice and rats, only a week after infection. Reaching the intestine a second time after their passage through the lungs, the larvæ, if in a host adapted to them, presumably settle in the intestine and complete their development until maturity is reached. If in a host not adapted to them, such as the mouse or rat, they quickly pass out of the host with the faeces.

Serious invasions of the lungs by *Ascaris* larvæ produce grave pneumonias, which often have fatal results in mice and rats. This cause appears to have induced death in a sucking-pig one week after being made to ingest many *Ascaris* eggs. It is not improbable that pulmonary diseases in babies, suck-

ing pigs and other young animals, may often be attributable to ascarides. The fact that the larvæ invade the lungs, as also other organs, in addition to the gastro-intestinal tube, and may cause a serious and even fatal pneumonia, indicates that these parasites have a greater pathogenic capacity than has hitherto been supposed.

Age is a very important factor in determining the susceptibility to infestation by ascarides; and the susceptibility diminishes greatly as the age of the host advances. This accords with the well known fact that infection by *Ascaris* is especially common in babies and sucking animals, while it is comparatively rare in men and in adult swine.—(*La Clinica Veterinaria*).

#### THE WORK OF THE BRITISH ARMY VETERINARY CORPS AT THE FRONTS.

By Maj.-Gen. Sir FREDK. SMITH, K C M.G., C.B., F R C V.S.  
(Reprinted from the *Journal of the Royal Society of Arts*)

When invited to deliver an address on the Veterinary Service in War, I doubted the necessity for so doing, for the subject had already been dealt with by Capt. Fairholme in 1915, by Lt. Col. Rainey of the Army Veterinary Service in 1917, and by Capt. Galtrey of the Remount Service in 1918. To Capt. Fairholme and Galtrey my Corps is indebted for their appreciative criticisms, while the public is under the obligation of receiving from their pens a picture of the veterinary care of animals in war which must have come as a revelation in humanity and organisation.

The popular conception of the Veterinary Service in war, prior to 1914, was not very creditable to human intelligence. I well remember a scientific friend expressing surprise that any organisation for the care of sick and wounded animals in war was necessary or practicable; he had a notion that something might be done for them during peace, but in the complexity of events associated with war nothing of a practical nature was possible, and the animals must be left to chance. Perhaps there were others of equal mental ability who thought the same, while it is certain that to the public generally the idea of any special organisation for the veterinary care of animals in war was altogether unknown. One of the objects of this paper is to show that the conservation of animal life in war is of paramount importance. It has not always been so regarded; up to and including the war in South Africa the history of the veterinary care of Army animals is sad reading, a story of suffering, misery and losses which can only fittingly be described as appalling. Humanitarian, and perhaps also financial, considerations are responsible for the change which has been wrought during the past sixteen years. I should not like it to be thought that the Veterinary Service was in any way responsible for this indifference. The veterinary reports furnished after every campaign for generations past dwelt upon the absence of all arrangements for the care of the sick, and the wastage resulting therefrom. They made suggestions for the future, and indicated the necessary organisation, but as a nation we are naturally slow to adopt new ideas, and intensely conservative; yet it is well known that disease and death are always more costly than health and efficiency.

We have, I am sure, to thank the factor of public opinion for the great change which has been brought about. For the best part of a century the same powerful lever has been working in the interest of the soldier, whose conditions of life have changed beyond all recog-

nition. If we wish to learn the lot of the soldier in war during the past and preceding centuries we have only to turn to the pages of Fortescue's "History of the British Army." How any men ever survived the absence of all organisation for their preservation and subsistence in little short of a wonder. Army animals have now had applied to them similar measures to those which have been found so successful and economical with men.

I have little doubt that there are many people who date the origin of the veterinary art from late in the nineteenth century, whereas, as a matter of fact, it is as remote in the history of the world as the beginning of historic times. I propose, very briefly, to take you over the ground, not only with the object of showing the antiquity of the veterinary art, but also of indicating the important part played in its development, during the early centuries of the Christian era, by veterinarians who were associated with the Army.

The earliest extant works on the diseases and injuries of horses belong to the fourth century of our era, and were written by army veterinarians of the Byzantine or Eastern Roman Empire, the chief of whom was one Apsyrus, veterinarian in the army of Constantine the Great. The fourth century was not, however, the real starting-point of veterinary knowledge; there is ample evidence to show that there were skilled men in the times of Ancient Greece. Xenophon had written on the care and management of cavalry horses 800 years earlier than the time of Apsyrus, and we know that his views, though twenty-three centuries old, are true to-day. Aristotle, who was contemporary with Xenophon, devoted the eighth book of his history of animals to a consideration of veterinary medicine; he wrote, of course, as a layman. The Romans, on the other hand, were not skilled in medicine or surgery; in fact, for five centuries the medical art was unknown in Rome, until they borrowed from Greece. If this was the condition of affairs in human practice, it is easy to understand the position of veterinary medicine. Varro, a soldier, who wrote in 36 B.C., and who appears to have explored every branch of human knowledge, refers to the ancient Greek veterinarians as "Hippiatroi." He was evidently familiar with their works, or which, unfortunately, nothing remains. He himself wrote on the diseases of animals, and it is doubtless due to such men that the Roman Army, in the second century of our era, possessed an infirmary for sick animals known as a "Veterinarium." But Columella spoke of the "Veterinarius," or animal physician, in 42 B.C. The irritating word veterinary is therefore extremely old; it disappeared with the final collapse of the Western Roman Empire, and is not met with again until the year 1528, though it does not appear in England until the closing days of the eighteenth century.

Among the contemporaries of Apsyrus was one Chiron, whose work on veterinary medicine has come to light only in recent years. Shortly after Apsyrus there lived a lawyer and gifted veterinarian, by name Hierocles, fragments of whose letters survive, and of whose works on diseases I have been fortunate enough to find two previously unidentified manuscripts in the British Museum.

Inspired by these gifted men, Vegetius, the Western Roman General, who flourished about the middle of the fifth century, wrote his remarkable treatise on "The Veterinary Art." He was not only a soldier, but a man of letters. Vegetius stands out in bold relief in the Western Roman Empire; deploring the low state of the veterinary art in Italy, he tells us that the study of animal diseases was regarded as a mean and contemptible occupation. Though 1500 years have passed since that was written, public opinion on this question has undergone very little change. The work of Vegetius may be read with interest to-day; he is very modern in some of

his views, such, for instance, as the absurdity of regarding outbreaks of disease as being evidence of Divine wrath. He urges the public in these cases to place their faith in medical aid, rather than in incantations and charms.

It is fortunate that, amid the disruptive influences of the following 1000 years, the work of Vegetius was spared. It was among the earliest books printed in Europe, being published in 1528. Two years later, what was left of the MSS. Byzantine veterinary writers, *i.e.*, Apsyrus, Hierocles, and their many correspondents, was published in Paris, under the orders of Francis I., the title then given to the collection being "The Hippiatrica." How these manuscripts got to Paris is unknown; probably, with many others, they were brought from Constantinople to Italy by the Greek scholars who fled at the fall of the Eastern Empire, and thence carried to France as loot during the Franco-Italian wars. It is interesting to note that a copy of the fragmentary manuscripts of these early Byzantine veterinary authorities is regarded as one of the literary treasures of the world.

This rapid, and necessarily very incomplete, outline will help to show you that the foundations of the veterinary art are not of recent laying, but belong to the history of the ancient world. As might be expected, army requirements stimulated interest in the matter. It was precisely during this period of the Hippiatrica, *i.e.*, the fourth century, that masses of cavalry were coming into existence, and largely replacing infantry in the line of battle. The growth of the cavalry arm, and the development of veterinary medicine and surgery, were not a mere coincidence.

I must not occupy your time by giving an account of the veterinary art from the Renaissance to the present day; but one important epoch in its history in this country cannot be passed over. In the last days of the eighteenth century—to be precise, 1791—a French refugee established a veterinary school in London, on the model of those then existing in France. Thus, for the first time in England, properly trained men were supplied for the veterinary care of horses. The opening of this school was welcomed by officers commanding mounted branches of the army. Troop horses had been decimated by contagious diseases, and the sole advisers were the ignorant farriers. Within five years of the opening of the London school, commissions in the army were given to its graduates. This was the beginning of the Army Veterinary Service, the development of which must occupy our attention for a few minutes, in order that its position at the present day may be understood.

At the end of the eighteenth century, and for many years afterwards, regiments were practically the private property of their colonels. It was they who engaged the necessary technical staff, such as surgeons and veterinary surgeons, and these officials, it is interesting to note, were actually remunerated by certain stoppages from the soldiers' pay. The Government of those days starved the army in every way, and insisted on its being self-supporting.

The method of caring for the sick animals of regiments on service was very simple. If they were not too ill to walk they were led along with the baggage; if too ill they were left behind to look after themselves. Nor need we be surprised at this primitive arrangement, when much the same system was employed in the case of the men. The long years of peace which followed Waterloo were not calculated to develop either the medical or veterinary branches of the army. Peace routine was simple: every regiment had its own separate accommodation for sick men and horses, and its own doctors and veterinary surgeons. The nurses in both cases were the untrained soldiers of the regiment.

The Crimean campaign revealed the impossibility of

attempting the regimental treatment of the sick and injured. The lesson had to be learned that sick men and horses are of no fighting value, a clog on mobility, and that the sooner they are moved into hospitals away from their regiments, the better for both regiments and patients.

For years after the Crimean War, thinking men in the medical service of the army were ever pressing forward a scheme by which the medical officers of the army were to be drawn from regiments, and converted into a homogenous body with subordinate technical staff under their own control, and hospitals under their own management and administration. Bitter and prolonged was the opposition to reforms of such obvious utility and humanity, but gradually each point was conceded until the Army Medical Corps was born. I need not refer to its magnificent work, nor the extraordinary manner in which it has controlled disease. It has recently been shown that in previous wars, from ten to fifteen men have died of disease to one who has died at the hands of the enemy; in the present war, one man has died of disease to every ten whose death was caused in the field.

It is self-evident that a scheme suitable for sick and wounded soldiers was capable of being adapted to the requirements of sick army animals. The Veterinary Service urged that its scattered and impotent components should be formed into a single body under its own officers, and given facilities for dealing with disease and injury on an organised basis. This scheme has taken nearly forty years to accomplish, and the only qualification I possess for appearing before you to-day is that I am the one survivor at present in active employment—though as a "dug out"—who has witnessed the entire transformation, and, further, I have been privileged to assist in its construction.

It is a remarkable fact that the people who are most anxious for the suppression of disease are those whose financial interests would appear to suffer seriously by its obliteration. More than two thousand years ago, Plato wrote that medicine was the science of health. The present position of preventive medicine in this country is due solely to the persistent hammering by the medical profession, which has resulted in the enormous improvement in the health of the nation, but much remains to be done. It may not be known to you that statistics have recently been published, which show that only one man out of every three in the prime of life is capable of being passed fit for service in the front line! This national reproach is far more difficult to deal with than unsoundness in horses, but even there, where the matter is under the direct control of the individual breeder, little but indifference has, in the past, been shown to the laws of heredity, so far as the affect the question of disease or transmissibility of unsoundness. The serious prevalence of consumption among our dairy stock is another reproach, of the removal of which at present there is no indication. Yet such is possible.

The fact is that the public do not appear to be seriously interested in the prevention of disease. Far otherwise is it in the question of treatment; they love medicine, especially nostrums, for which they are cheerfully prepared to pay the Exchequer £200,000 a year in stamp duty alone! Similarly, the entire function of the veterinary profession, according to the public view, is the treatment of disease. I am anxious to remove this erroneous conception, and to impress upon you that its great office is prevention. From the date of the first Army Veterinary Service in 1796, the campaign against disease has been going on. As we have seen, it was the appalling losses due to contagious diseases among troop horses which created the Service, and within a few years of its formation matters had improved beyond recognition.

Every step in the fight against disease has to be based upon precise scientific knowledge. Very occasionally a truth is obtained by accident, as, for example, the protection afforded against smallpox by inoculation with cowpox, but accidental discoveries are rare. It was the patient study of the mosquito, flea, louse, and bed-bug which showed their connection with malaria, plague, trench fever, and typhus. It was the study of certain species of blood-sucking flies and ticks which revealed the true nature and origin of a series of plagues which still remain incurable, and are capable of destroying the whole human and animal life of a sub-continent.

I am endeavouring to show that the importance of veterinary hygiene and veterinary preventive medicine has been overlooked by the public. These play the largest part in the work of the Army Veterinary Service, for the chief losses among animals in war are not due to battle casualties, but to disease and injury. Contagious diseases have to be guarded against by the careful inspection of all animals, their introduction into the Service has, if possible, to be prevented, and should they gain admission, their early detection and obliteration is of paramount importance. In times of peace this is not difficult, but in war it is otherwise, for not only are the risks of infection much greater, but the facilities for proper inspection are infinitely less perfect. Moreover, there is a daily risk of fresh infectious material being introduced by the constant influx of new animals to replace wastage.

Injuries are controlled by a precise knowledge of how they are produced. Let me illustrate this point, which otherwise would appear to be a mere platitude. Sore backs, sore shoulders, head-rope galls, and kicks from other animals, are among the prolific sources of injury in the field. The trained eye can recognise at a glance an ill-fitting saddle or collar; it can recognise a head-rope so fastened that it is bound to cause injury, and can prescribe means of restraint for kicking horses which considerably limit their activities. Knowledge of this kind is designated "horsemastership," and the man who possesses it is a valuable asset to the State. He must also understand how horses should be fed, acquire an acquaintance with the various foods employed, and the elementary principles of nutrition. He must always be learning, for these questions are not so simple as might appear, and the knowledge cannot be acquired by reading. An apprenticeship of five years under a good horsemaster is necessary, in order to gain a working acquaintance with the subject. Two thousand three hundred years ago Xenophon wrote that the eye of the master makes the horse fat. This is an axiom in horsemastership, for there is nothing capable of taking the place of constant supervision. We must remember that when animals are tied up they cannot look after themselves.

(To be continued.)

#### NORTH MIDLAND VETERINARY ASSOCIATION. (NATIONAL V.M.A.—NORTHERN BRANCH).

A meeting was held at the Grand Hotel, Leopold Street, Sheffield, on Tuesday, December 17th.

Prior to the meeting the members present were entertained to tea by the Sheffield Members of the Association.

The following were present:—Messrs. W. Collinson, President, T. C. Fletcher, M. Robinson, and F. L. Somerset, Past Presidents, R. Hudson, Vice-President, J. S. Lloyd, Honorary Secretary, H. Thompson, Honorary Treasurer, and T. Bowett, G. J. Furness, S. E. Sampson, and C. S. Smith. Mr. J. Malcolm Armfield was present as a visitor.

Before beginning the business of the meeting, the President proposed a vote of condolence with the Hon-

orary Secretary in the loss he had sustained by the death of his daughter, which was carried in silence by the members standing. Mr. Lloyd thanked the members for their vote.

The Minutes of the last meeting having been printed and published, were taken as read, and on the vote of Mr. Thompson, seconded by Mr. Robinson, were adopted. The report of the Council Meeting held on October 15th, was read by the Honorary Secretary and signed by the President.

Apologies for inability to be present were received from Messrs. Ludlow, Murgatroyd, Nixon, and Wheatcroft.

#### ELECTION OF OFFICERS.

Mr. F. L. Somerset proposed and Mr. Smith seconded that the retiring President, Mr. W. Collinson, be re-elected. This was carried unanimously, and Mr. Collinson thanked the members for his re-election.

Mr. FURNESS proposed and Mr. ROBINSON seconded that the other Officers be elected *en bloc*, as suggested in the Minutes of the Council, and this was carried.

In effect the Officers for the year 1919 will be as follows:—

President: Mr. W. COLLINSON.

Past President: Mr. T. C. Fletcher.

Vice-Presidents: Messrs. R. Hudson and S. H. Nixon.

Hon. Secretary: Mr. J. S. Lloyd.

Hon. Treasurer: Mr. H. Thompson.

Auditors: Messrs. S. E. Sampson and W. Murgatroyd.

Council: Officers Ex-Officio, and Messrs. Bowett, Furness, Marrison, Robinson, Smith, and Somerset.

#### VETERINARY FEES.

After some discussion it was agreed that the fees decided upon at the last meeting should stand. This practically amounts to an increase of 50% upon pre-war charges.

Regarding fees paid by Insurance Companies, it was unanimously agreed that the lowest fee to be accepted should be 5/-: mileage to be charged extra if the distance travelled is over three miles, it being understood moreover, that special visits should not be made in connection with these cases, but that the examination should be made when the practitioner was in the neighbourhood.

#### NOTES ON CASES.

In the absence through illness of Mr. S. H. Nixon, who had promised some "Notes on Interesting Cases", it was decided to proceed with the subject, and the President called upon members generally to carry on the discussion.

The PRESIDENT related the facts of an interesting case of Tetanus. He injected ant-tetanic serum into the near jugular vein and this caused the animal considerable uneasiness, sweating, etc., which in a short time passed off. The next morning he found the opposite fore leg considerably swollen, as if the animal had an attack of Lymphangitis. The mare recovered from the Tetanus, but the leg continued swollen and she only moved with difficulty. The animal was forced to use the leg and ultimately did well.

He also gave an account of a Skye terrier which was brought to his premises for board and left three weeks, whilst in his possession being exercised only on the chain. The animal was sent home and also exercised from there on the chain but soon developed symptoms like Strychnine poisoning. It was ascertained that the animal had been fed on the flesh of a cow that had been treated with Nux Vomica. The dog died but no analysis was made. He wondered whether the symptoms were due to the Nux Vomica.

Messrs. FURNESS and SOMERSET remarked that they thought dogs were very susceptible to Strychnine.

Mr. SOMERSET also mentioned the case of a Persian cat which had stoppage of the bowels, and in which he

attempted to give an enema but found he could not insert the syringe. There was a history of a foreign body, and under the X Rays a needle was discovered. It was not possible to remove the needle, and the cat had to be destroyed.

Mr. ARMFIELD mentioned a case of vomiting in the horse through the nose and mouth.

The HONORARY SECRETARY stated that he had seen a case of vomition in the horse caused by eating young clover. The only treatment given was chlorodine and bi-carbonate of soda, and when he visited the animal the next morning he found it quite healthy.

Mr. R. HUDSON had seen a case due to feeding on mangolds, but in this case the animal died. A post-mortem examination was made and it was found that there was no rupture of the stomach, but its contents were of a very fluid nature.

The PRESIDENT mentioned Lang's treatment by the stomach tube and the administration of sodium chloride solution, and stated that he had passed a cattle probang in a case of distended stomach with good results.

Mr. THOMPSON related the history of several horses which had been "tubed" in which he had seen quantities of water passing down the trachea into the lungs whilst drinking. No evil results seemed to follow.

Mr. HUDSON had treated suppressed abscess through the tracheotomy tube with good results.

#### LYMPHANGITIS.

Mr. FLETCHER initiated a discussion, and wished to know if anyone had used common salt for treating such cases, and particularly where the leg remained considerably swollen after the acute symptoms had passed off.

Mr. SOMERSET stated that he had good results in such cases with sulphate of soda.

Mr. THOMPSON and Mr. FURNESS thought work or forced exercise was wanting.

The HON. SECRETARY stated that he had good results from two drachm doses of Aloes every other day, but considered nothing would decrease a thick leg once fibrous tissue had been formed.

The treatment adopted by Mr. Furness was to give a dose of physic (aloes) followed by doses of Iodide of potass twice daily.

Mr. SAMPSON did not like big doses of aloes in old old horses; his experience being that they often proved fatal. He generally gave Hyposulphite of soda.

The PRESIDENT, on the other hand, stated that he gave a first dose of five drachms of Aloes, and repeated it in 48 hours. As soon as the action of the Aloes had passed off he put the animals to work.

It was generally agreed amongst the members present that lymphangitis is not now so common as before the war, and some of them thought this was probably due to the absence of beans in horse-food mixtures.

Mr. THOMPSON stated he had lymphangitis in batches owing to the horse having been fed upon carrots.

Mr. SOMERSET mentioned a case of an ambulance horse that had had lymphangitis about six times. He was afterwards sold to a grocer who kept him in poor condition and gave him hard work, with the result that he was now free from the disease. While doing the ambulance work he had a first attack of lymphangitis which was treated with six drams of aloes followed by nitrate of potass, and put to work. The next week, or in a short time after, another fore leg was attacked and was successfully treated in the same way. Repeated attacks, however, left a thick leg behind. He thought lymphangitis was something like gout.

Mr. ARMFIELD mentioned a case where fibrous tissue developed to such an extent as to interfere with the action of the flexor tendons, causing the animal to have an over-shot fetlock.

Mr. FLETCHER wanted to know if anyone had seen lymphangitis of the bowels.

Mr. HUDSON thought a probable cause of lymphangitis was plugging of the iliac arteries.

The HON. SECRETARY considered that the symptoms of lymphangitis as shown by pain and sweating of the leg was due to inflammatory action in the lymphatic vessels, and considered that the swelling afterwards was due to inability of the lymphatics to carry away the exudations.

#### INTERESTING SPECIMENS.

Mr. SAMPSON showed the superior maxilla and pad of a three-year old bull affected with actinomycosis in the upper palate. He administered 20 grains of Bin-iodide daily, and painted the mass with carbolic phenol. The growth increased, and involved the nostrils, and in consequence the bull had to be slaughtered. A post-mortem examination revealed the animal to be also affected with advanced tuberculosis. [Since the date of the meeting, the specimen from the bull has been submitted to Sir John M'Fadyean for his examination, and he has reported that the disease was undoubtedly actinomycosis. The animal was thus suffering from two diseases at the same time.] He had been bought for stock purposes in the North of England, and he wondered whether he had been a tuberculin "reactor." He had known several good bulls which had been bought cheaply and afterwards found to be tuberculous. In his opinion it pointed to the fact that these bulls had been tested probably for overseas trade, but having failed to pass the test, were sold in this country for stock purposes.

Mr. SAMPSON also continued his remarks from a previous meeting regarding the case of a bull with one testicle. Attempts had been made to get the seller to return part of the purchase money, but he declined to do anything as the condition was not hereditary. He thought it would interest the members to know that this bull was now serving cows with success.

A vote of thanks to the President concluded an interesting meeting.

J. S. LLOYD, Hon. Sec.

#### TEACHERS AS COUNCILMEN.

*To the Editor of "The Veterinary Record."*

Dear Sir,—The Editorial in your issue of the 1st inst. appears to be a combination of two efforts—to stifle criticism of the Council of the R.C.V.S., and to laud and magnify the qualifications and abilities of teachers, or, as you call them, "Schoolmen," as Councillors. If I may be allowed your hospitality, I wish to state most candidly, that I do not think that the opinions which you advance and espouse so emphatically, are supported by the majority of the profession.

A correspondent, who is obviously only expounding his own views, expects, and is allowed considerable latitude therein, as it is not of great consequence, whether he is voicing the collective views of his fraternity, or merely playing a solo; but in the editorial of a professional paper one expects an expression of opinions, which, although probably conservative, are also unbiased and tolerant; qualities that are not conspicuous in the article I refer to.

To speak of criticism of the Council as, "Indulging in general disparagement," and as a "Vagary," and "Derogatory," savours more of the ponderous and theatrical magnificence of the Petty Sessions, than of the editorial sanctum, and it will indeed be a sad day for the profession if we must withhold our views, lest we incur the chastisement of the editorial rebuke.

What you also term with magnificent scorn, "this sort of thing," appears to be that zoological curio, popularly known as a mare's nest, which, although seldom seen, is hardly worthy of the editorial thunder. You proceed to repudiate a view, which I am not aware has

been seriously advanced, that "teachers of the Council care for nothing beyond school and examination questions;" although I am prepared to admit unreservedly that they may be as interested in the general policy of the Council as much as any other class, it would indeed be passing strange, if they did not consider these questions, in which they are presumably well versed and highly interested, of paramount importance, and who shall say, that from their point of view, they are not right? This much may be granted, but that, "they would still be indispensable," requires some swallowing.

Word values change with the times, and the most striking contemporary instances of such change, may be found in the recently ubiquitous words, "contemptible," and "indispensable," the former, used as a noun to imply a character almost beautified in its modern meaning, and in its pre-1914 sense, as a fitting adjective to qualify the latter in its "tribunal" usage. I should be loath to apply the latter meaning to the teacher Councillors, but, with no ill-will, submit that it is as accurate as your description, and equally ridiculous.

Your next statement, "Matters which profoundly affect the future of the profession, are quite as important as anything concerning its present; and the most aggressively 'energetic,' practitioner can hardly claim that he and his kind are so well fitted to deal with them as school men," is to point, with a vengeance.

Had you here had the benefit of an interlocutor, to cry forth that classic aphorism, "That's the stuff to give 'em," I do not think that even the most brazen of those ignorant nonentities, the aggressively energetic practitioners, would have dared to speak again on the subject, unless perhaps, with great humility, to recant his former absurd, and heretical opinions. As I make no pretensions to be either aggressive or energetic, may I ask you to substantiate this new dogma?

By what process of second sight, occultism, necromancy, or alchemy are the "schoolmen"—(like Councilmen, a strange and cumbersome union, savouring of the Hun principle of compounding words)—enabled to see into the future, any farther than other practitioners, aggressive or otherwise? And why are "he and his kind" less fitted to deal with such matters than the teachers?

With lavish hand, in the best demagogic manner, you propose to distribute what is not yours to dispose of, i.e., the seats on the Council, when you state, "the interests of different schools occasionally clash, and it is therefore desirable that each should have at least one representative." One is grateful that you should have limited the number, for if your argument is sound it might seem only reasonable that the schools should have two, or three, or more representatives each.

It is well that you have previously given the knock-out blow to the aggressively energetic practitioner, otherwise he, with that crude coarseness typical of "he and his kind," might ask what on earth the clashing of different school interests has got to do with the Council. Or even suggest that the floor of the National Sporting Club is a more suitable arena for the settlement of these squabbles.

The statement that, "These reasons alone render a good school representation imperative," is rendered nugatory by the fact that few people will accept them as reasons, but only as a grossly biased and pragmatic expression of opinion, unsupported by facts.

The query, "But who has greater opportunities of obtaining such knowledge (of the necessities of the profession) than he" (the teacher)? is answered to your own satisfaction by your statements, that:—

(a) "He works in a large city where he may meet many more Veterinary Surgeons than are to be met with in any country district."

This is truism, and is equally applicable to all his fellow citizens in the profession.

(b) "Often his work,—especially if he is a pathologist or clinician, brings him into contact with veterinarians much farther afield."

The bringing into contact may be conceded, but, that the necessities of the profession are the chief subjects of discussion may be queried: it is much more likely that when the subject of consultation is settled, that politics, racing, or vintages, are the topics discoursed on. Readers of Shakespeare will have observed, that when two or three men are gathered together, the conversation generally turns upon the fair sex: may I with great timidity and all humility, (if my query is not so irreverent as to verge on the profane)—ask, if it is not just possible, that on the occasion of these meetings our intellectual giants do not sometimes also revert to type, and exchange a few pleasantries on, "The Ladies, God bless them."

(c) "Often also, he keeps in touch with many of his old students; and this in time, greatly extends his professional acquaintance."

This also is true, but like the former point, does not imply any widening of knowledge of professional needs, and if indeed in both cases, such needs are the only topics of conversation, the knowledge acquired is only second hand, and is merely the crumbs which fall from the table of knowledge, of the general practitioner.

(d) "The truth is that hardly any man is so well able to gain a wide and intimate knowledge of the condition and requirements of the profession as a teacher, especially if in a large school."

Having thus given the *coup-de-grâce* to the smaller schools and their representatives the field is somewhat clearer; it would however have been simpler to limit your advocacy in the first case solely to a large representation of teachers from the largest school, whichever that may be, and to let the smaller fry disappear into oblivion, along with aggressive and energetic practitioners, and those from the country, who are denied the mental sustenance and enrichment, which are apparently only to be found in large cities.

(e) "Compared with his opportunities, those possessed by the great majority of practitioners are insignificant."

This is highly debatable, but even if correct it must be stated, that is not the number of opportunities given, but the manner in which they are made use of that counts, and unless evidence is produced to enable us to judge on this point, many, like myself, will consider your statement of doubtful value.

(f) "Add to this the fact that teachers are usually men of more than average natural ability; and it is easy to understand their potency in the Council chamber."

This is sufficient to finally choke off anyone with a hideous pachydermatous than that of Lord Haldane, but as it is well known that fools rush in where angels fear to tread, I propose to have a rush.

If you mean that teachers, like other veterinary surgeons, are of more than the average ability of men outside the profession, I heartily agree, but if you wish to assert, that teachers are of a higher ability than their professional brethren, your views are only spared from being dedicated as an insult to the profession, by their crude absurdity.

Your final paragraph is so ingenuous, and so very definitely non-committal, as to be worthy of ranking with Counsel's opinion.

I wish to emphasise that I have nothing but the best of good feelings towards the teachers in our schools: in great part their devoted services are not performed in the lime light, and probably their great work for the welfare of the profession is apt to be overlooked, especially those whose names are seldom brought to our notice. I feel sure that many teachers must possess qualities which render them peculiarly well fitted as Councillors, not because, but rather, one might say, in spite of, the

fact that they are teachers. Had you limited your advocacy to that point, I should not have ventured to emerge from my obscurity, but, that teaching is a prime qualification for a seat on our Council, is a doctrine which I cannot subscribe to.

It has been stated of lawyers, that, "they see too much of life in one way, too little in another, to make them safe guides in practical matters. Their experience of human affairs is made up of an infinite number of scraps cut out of other peoples lives." These words may with equal truth be applied to teachers.

Mankind has frequently been divided into classes: in the early days of the Christian era, the dividing line parted the sheep from the goats. P. G. Woodhouse classifies mankind as men who can stop dog fights and men who can not do so.

Rudyard Kipling's division is, Human Beings and Germans, but apparently your cleavage is the separation of science from brute force, when you divide the profession into "teachers," and "the great majority of practitioners."

It is with the greatest reluctance that I assume the office of press correspondent, for which I possess neither inclination nor aptitude, but as I regard your attack on the great majority of the profession, and your unfavourable comparison of their abilities with those of the teachers, as being in the most questionable taste, I feel impelled to enter the lists, in defence of myself and my non teaching colleagues, at whom you have so contemptuously, thrown down the gage.

It was, I believe, Disraeli, who delivered the delightful dictum, that, "The worst of great thinkers is that they always think wrong," and it would be charitable to assume, that the wrongness of your views is solely due to the greatness of your thoughts.—I am, Sir,

Yours faithfully,

A. B. MATTINSON, Major, R.A.V.C.,  
Commandant School of Farriery.

Woolwich, S.E. 18. 5/2/19.

[We print the foregoing as a contribution to the argument; it is amusing, but it occupies much space, and it does little to elucidate the main question, upon which there is a distinct difference of opinion—Is it desirable that the teaching colleges should be represented at our Council board?]

#### ARMY VETERINARY SERVICE

War Office, Jan. 30

The following dispatch has been received by the Secretary of State for War:—

General Headquarters, Salonika, Nov. 1, 1918.

My Lord,—I have the honour to submit here a list of the names of the Officers whose services I desire to bring to your Lordship's notice for gallant conduct and distinguished services rendered during the period from March 1, to October 1, 1918.

I have the honour to be, my Lord,

your Lordship's most obedient servant,

G. F. MILNE, Lt.-Gen.,

Commanding-in-Chief, British Salonika Force

Col. (temp. Brig.-Gen.) F. Essie, C.B., C.M.G., D.S.O.; Temp. Capt. (actg. Lt.-Col.) D. O. Turnbull, D.S.O.; Temp. Capt. T. B. Harries; Maj. W. L. Harrison, O.B.E., F.R.C.V.S. (T.F.); Temp. Capt. A. A. Higgins (died); Temp. Capt. G. N. Jull; Temp. Capt. H. B. Kauntze; Temp. Capt. G. Moir, O.B.E., F.R.C.V.S.; Capt. R. H. Penhale (T.F.); Temp. Capt. J. Richardson; Capt. (actg. Maj.) P. R. A. Thrale (T.F.).

War Office, January 31.

The following dispatch has been received by the Secretary of State for War:—

General Headquarters, Sept. 30, 1918.

My Lord,—I desire to record my appreciation of the excellent services rendered by the Officers included in the list I am forwarding with this Dispatch, during the period from December 1, 1917, to July 31st, 1918.

I have the honour to be, my Lord,

your Lordship's obedient servant,

J. L. VAN DEVENTER, General-Commanding-in-Chief,  
East African Force.

STAFF—Temp. Capt. F. J. McCall, M.C., E.A.V.C.

Capt. A. M. Howie, S.A.V.C.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Jan. 30.

REGULAR FORCES ROYAL ARMY VETERINARY CORPS

Capt. F. W. C. Drinkwater (T.F.), to be actg. Maj. whilst holding the appt. of D.A.D.V.S. (Nov. 1, 1918).

Temp. Lts. to be temp. Capt. :—S. H. Pettifer, J. J. Clune, G. P. Kennedy, J. P. A. Morris (Jan. 15).

Jan. 31.

Temp. Capt. T. A. Huband, F.R.C.V.S., relinquishes his commn. (Jan. 7,) and retains the rank of Capt. (Substituted for notification in *Gazette*, Jan. 6.

Feb. 3.

Maj. and Bt. Lt.-Col. W. A. Wood relinquishes the actg. rank of Col. on ceasing to hold the appt. of D.D.V.S. (Nov. 22, 1918).

Maj. and Bt. Lt.-Col. P. J. Harris to be actg. Col. while holding the appt. of D.D.V.S. (Nov. 22, 1918).

Capt. (temp. Maj.) A. Spreull D.S.O. (T.F.), to be actg. Lt.-Col. while holding the appt. of A.D.V.S. (Dec. 3, 1918).

Capt. P. T. Lindsay, Spec. Res., to be actg. Maj. while holding the appt. of D.A.D.V.S. (Dec. 7, 1918).

Feb. 4.

Capt. L. A. Auchterlonie relinquishes the actg. rank of Maj. on ceasing to comd. a Vety. Hosp. (Jan. 20).

Feb. 5.

Temp. Capt. W. H. James, D.S.O. relinquishes the actg. rank of Maj. on ceasing to hold the appt. of D.A.D.V.S. (Nov. 11, 1918).

Capt. J. H. Thomson (T.F.), to be actg. Maj. while holding the appt. of D.A.D.V.S. (Nov. 11, 1918).

The following temp. Capt. relinquishes their commns. on appt. to the Aust. Imp. Force:—J. J. Bourke (Dec. 7, 1918); Bt. Maj. S. L. Symonds (Dec. 18, 1918).

D. S. Rabagliati to be temp. Capt. without pay or allowances (Feb. 5, 1916).

SPECIAL RESERVE OF OFFICERS.

Jan. 31.

Lient. to be Capt. :—J. D. Haywood (Jan. 16).

Feb. 1.

Capt. R. Moore is placed on the retired list on acct. of ill-health caused by wounds (Feb. 2).

TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Jan. 29.

Major W. L. Harrison, O.B.E. F.R.C.V.S., to be actg. Lt.-Col., whilst A.D.V.S. (Jan. 21).

Bt. Maj. (temp. Maj.) G. W. Godwin relinquishes the temp. rank of Maj. on ceasing to be empld. as D.A.D.V.S. (Sept. 29, 1918).

Temp. Capt. H. Leeney is retired, having attained the age limit (Feb. 5), and retains the rank of Capt.

### NOMINATIONS FOR ELECTION TO COUNCIL, JUNE, 1919.

Eight Vacancies.

Candidates.	Proposers.
BRADLEY, O. C., Edinburgh	J. Abson, H. Sumner
CRAIG, J. F., Dublin	D. S. Prentice, T. H. Griffin
DUNSTAN, J., Liskeard	O. C. Bradley, S. Stockman
GAIGER, S. H., Glasgow	S. Stockman, P. Wilson
GOFTON, A., Edinburgh	F. W. Garnett, A. L. Wilson
HAMILTON, D., Hamilton	O. C. Bradley, P. Wilson
HILL, J., Llanelly	D. G. Davies, J. F. Rees
LAWSON, A., Manch'r	F. W. Garnett, J. W. Brittlebank
LOGAN, W., Inverness	R. J. Sturdy, L. L. Dixon
MALE, G. P., Reading	G. A. Banham, J. C. Coleman
STOCKMAN, S., London	F. W. Garnett, R. C. Trigger
TUTT, J. B., Winchester	E. W. Baker, T. B. Goodall
WHARAM, S., Leeds	S. E. Sampson, J. Clarkson
WILLETT, J., London	J. T. Share-Jones, H. Sumner

*Subscriptions to R.C.V.S. are unavoidably held over.*

### Personal.

**HOWIE—HANNAY.** At the Grand Hotel, Charing Cross, Glasgow, on the 4th inst., by the Rev. James Hutchison, M.A., Cambuslang, assisted by the Rev. William Baxter, M.A., Barrhead, Adrian Morrison Howie, M.R.C.V.S., Capt R.A.V.C. (late South African Veterinary Corps), only surviving son of Mr. and Mrs. Thomas J. Howie, "Auchinblae," Kirkburn Avenue, Cambuslang, to Agnes McCall Ney (Nancy), eldest daughter of Mr. and Mrs. John W. Hannay, "San Remo," Stewarton Drive, Cambuslang.

### OBITUARY.

**PATRICK DESMOND ENGLISH, M.R.C.V.S.,** Queenstown, Ireland. Graduated, Dublin: July, 1911.

Mr. English died 28th Nov., 1918, Aged 30.

**E. GRANVILLE HASKELL, M.R.C.V.S.,** Bury St. Edmunds. Lond: Dec. 1904.

Death occurred 26th January, at the age of 44.

**ARTHUR GOULÉ, G.V.S.,** Pretoria.

Lond: April, 1871.

The loss is reported of Mr. Arthur Goulé; torpedoed on "Galway Castle," en route to South Africa, on Sept. 12th, 1918.

**ALFRED MALLER, Hove, Brighton,**

"Existing Practitioner."

A correspondent writes:—"Mr. Maller died here (Hove), on Saturday last, Feb. 1st; he was in his 88th year, and was engaged in his practice until about six weeks ago. He had been in practice here for over 60 years." He was always well spoken of by members who came in contact with him professionally.

**HENRY PULMAN, Nelson, Lanes.**

"Existing Practitioner."

Death of Mr. Pulman took place on 31st January.

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1597.

FEBRUARY 15, 1919.

VOL. XXXI.

## ELECTION PROPOSALS.

Two old proposals are to-day revived in an election address. The first is that, when the passage of the Bill affords the necessary funds, the "out-of-pocket expenses" of members of Council shall be paid. Probably most men will agree with this in principle, at least to some extent. There is much to be said against remunerating Councilmen for their services, for one having the interests of the profession at heart would not grudge the few days each year which Council work demands; but the payment of expenses is another matter. "Actual out-of-pocket expenses" is a somewhat elastic term; but the railway expenses of all Councilmen living fairly out of London ought certainly to be met by the College as soon as our funds allow; though even that will amount to no small annual disbursement.

The second proposal—of splitting up the profession into electoral divisions on the Parliamentary plan, is an older one. It has appeared before at times when the profession felt vaguely dissatisfied with the Council; and has died away before long, as it probably will again. Plausible as it may appear at first sight, it will not bear close examination. Our present system is that the candidate appeals to the whole profession, promises to work for its interests as a whole, and is elected by votes coming from all over the Kingdom, and beyond it. That is the widest possible basis for the election; and any narrowing down of it would be injurious. The long-established practice of the Professional Societies nominating candidates for Council elections has not done much good to the Council itself. Such candidates have been elected, often largely and sometimes wholly through the influence of their Societies. Some have been good men; but, speaking very generally, a great many have not been legislators of the broadest views. A system under which every candidate is not merely nominated but actually elected by a small section of the profession would tend to produce Councilmen of still narrower type. Under our present system, a Councilman at least knows that the whole profession placed him in his seat and can remove him from it, and will probably take something like an all-round interest in the profession. Under the local plan, he may ignore all interests save those of his "constituency." Moreover, though there are many questions which concern some sections of the profession more than others, there are few in which the interests of different sections directly clash; and this nullifies the chief apparent reason for a division of the electorate. There are no grounds for supposing that division would improve the Council in any

direction; there are solid grounds for believing that it would do the reverse.

Our voting system, under which the members choose a quarter of the Council every year, is as perfect a method of enabling the whole profession to constantly influence its governing body as could be devised. Doubtless it often returns the wrong man to the Council; but it does so not from any faults in the system, but from errors in the judgment of the very human electorate.

## MATRICULATION EXEMPTIONS.

A correspondent criticises the recent exemption from matriculation of three prospective veterinary students, subject to "satisfactory testimonials as to general education" being received. The present conditions are unprecedented and there can be little harm in the few exemptions that have been made, always providing that good evidence of a liberal education is forthcoming.

Schoolmasters' testimonials, which are also in a sense certificates of work done, and are not necessarily given with reference to any one profession or calling, supply this. The Examination Committee judge each case on its merits, and there is no reason to think that each is not scrutinised keenly. That such scrutiny should also be sympathetic goes without saying; for, if ever men did deserve special consideration, these do.

## GOING THE WRONG WAY.

In the report of the proceedings of the N.M.V.A., in the current issue of *The Record*, February 8th, there is a note by Mr. Thompson regarding some horses which had been "tubed," and in which he had seen quantities of water passing down the trachea into the lungs whilst drinking, and that no evil results followed. It is to be regretted that more particulars of these cases were not given, as the question is an interesting one. Some years ago there was a note in one of our weeklies of a similar occurrence, and here also no harm seems to have resulted.

We "tubed" a mare in 1914 within a few hours of the apparent onset of a very severe attack of strangles. For the next two days the patient took nothing, and from the third to the sixth day only fluids—mainly milk. After each effort at swallowing, a little stream of milk would come through the opening in the trachea, and doubtless more passed down. The mare never coughed or seemed to be inconvenienced in any way from the presence of these fluids in the trachea. When an abscess formed and the pus was evacuated, liquids ceased to come through. At this date, 1919, the mare is quite well.

The history of these cases seem to suggest that the passage of fluids into the trachea during efforts to swallow, in severe sore throat in horses, is commoner than is generally supposed; and also that it occurs in many other cases where medicines in a liquid state are forcibly administered, especially with horses. The question whether "pneumonia" follows in any of these instances would appear to depend on the nature of the fluid passing down rather than upon the quantity; so that in prescribing we should always have in view the possibility that a part of our drench may "go wrong" and accordingly avoid irritating substances or giving concentrated solutions.

It is a veritable *catastrophe of medicine* to see an animal recover from an acute attack of a given disease, and then to have to stand by and see the patient "pass out" from some pulmonary trouble induced during efforts to relieve the original condition. We saw some time since two horses die in one stable within a few weeks of each other from this cause. The attendants raised the head by means of a small pulley; and of course the horses were quite unable to get their heads down until the drenching had finished. The draught contained ammonia, and in our experience this is one of the worst agents to go the wrong way. Capsicum, in even small quantities, is also most injurious. Mag-sulph. in strong solution induces pneumonia in cows, but in dilute solution does little harm; and salt seems to occupy a similar position.

In one instance we know of ten young bullocks were each given half-a-pint of linseed oil, with the result that two died almost immediately. The oil must have entered the trachea in bulk, and no doubt it suffocated the animals. It was purely a case of carelessness in drenching.

We have seen more drench catastrophes in the horse in cases of acute gastric disease than in other conditions; here the animal sometimes obstinately refuses to swallow, and the medicines used are often of a strongly irritative character and, as a rule, given in rather a concentrated form, so that on entering the trachea they are very likely to induce trouble. The extended use of medicines in capsule form seems desirable in horse practice.

Contrary to what might be expected, an animal may not give an immediate indication that something has gone wrong. A rigor may be first symptom; then follow cold sweats and dyspnoea. The absence of cough in some instances is noticeable, and is apt to mislead. The facial expression is characteristic; in an hour or two the animal looks years older. No food is taken, and the animal remains in one position, or moves with a grunt. The temperature is at first unreliable in forming a prognosis, but it usually remains high as the case develops. If the animal is not well at the end of twenty-four hours the prognosis is often grave. In estimating the chances of recovery one must know something of the character of the agent swallowed, for it seems clear from the evidence that the mere entrance of a bland unirritating fluid into the trachea in moderate amount is a matter of little importance.

F. T. HARVEY, F.R.C.V.S.

## DROPSY OF THE UTERUS IN A EWE.

*Subject.* A valuable Lincoln ewe.

*History.* Died the night previous, attempting to give birth to three lambs.

*Post-mortem.* Revealed womb greatly extended, containing in addition to three fine lambs, ready for birth, about five gallons of clear, slightly green, practically odourless fluid.

Liver showed fairly extensive fatty degeneration, and pitted on pressure. Kidneys rather large and flabby, otherwise normal.

The carcase was normal in other respects.

I have heard that this condition is sometimes produced by excessive feeding on turnips, but do not know that this was the case in this subject.

We sometimes find a similar condition in cows sent to the Sheffield slaughter-houses.

It would be interesting to hear if other veterinarians have observed this condition, and to have their opinions concerning the same—prevention, etc.

J. MALCOLM ARMFIELD,

Town Hall, Sheffield.

Assist. Vety. Insp.

## ABSTRACTS FROM FOREIGN JOURNALS.

### THE ETIOLOGY AND PATHOGENY OF RACHITISM.

De Biagi Fernando contributed an interesting article upon this subject to the *Revista Medica* for 1917. There is a theory that rachitism depends upon a disturbance in the function of the glands of internal secretion, and especially of the thymus, supra-renal capsules, and thyroid glands. So far back as 1858, Fredebleu sought to establish a connection between the function of the thymus and the development of the osseous system; but it may be said that the true origin of the thymic theory of rachitism is due to Basch. He observed that in rabbits and dogs, four or five weeks after the ablation of the thymus there were alterations in the general development, and in the case of fracture of bone disturbances in the formation of the callus. From this he concluded that the thymus gland throws into the circulation a substance which may exercise an important function during the period of growth. But the administration of fresh calf thymus to rachitic patients gave no results to Stolzner and to Lissauer; and later experiences demonstrate that, though disturbances of the thymus may have influence upon the general growth and upon the calcification, we cannot certainly find any co-relation between these disturbances and rachitism.

At a later date, importance was attached to insufficiency of the supra-renal capsules, the office of which seemed to be to regulate organic changes and the metabolism of the various tissues and animal organs.

Stolzner was the first to treat rachitism with extracts of supra-renal capsules, and obtained satisfactory results. He observed improvement of the

craniotabes, eruption of the teeth, and subsequent diminution of the fontanelle, of the thoracic deformities, and of the alterations of the epiphyses.

Prof. Bossi, of Genoa, having in repeated experiments upon sheep constantly observed that the ablation of one supra-renal capsule provoked a true osteo-porosis, treated several cases of osteo-malacia with extract of supra renal gland, and obtained not only improvement, but true clinical recovery. These results suggested the use of supra-renal extract to avoid osseous deformities, especially of the pelvis, which are observed in infancy from rachitism; and this treatment was observed to give favourable results. Other workers afterwards took it up with success. Jovane and Pace, in Naples, and Mauro Greco, in Jemma, came to the conclusion that supra-renal treatment improved the nutrition of rachitic patients, stopped the osseous pains and the gastro-enteric disturbances, caused the disappearance of the softening of the tissues, and favoured walking. Luzzatti, in Concetti, also administered tabloids of supra-renal extract, and was satisfied with the result.

According to another theory, rachitism depends upon insufficiency of the thyroid gland. The substance elaborated by this gland may have a stimulant action upon growth in general, and particularly upon the growth of the bones. In congenital myxoedema, there is an arrest in the development of these, and ossification remains stationary. Hofmeister has demonstrated that the same thing also occurs in young animals in consequence of extirpation of the thyroids. Quite the contrary occurs in hyper-thyroidism, where the growth of the skeleton is accelerated. On the other hand, Hertoghe reports good results from the thyroid treatment of rachitism. But other observations have proved that this treatment is of use only when the rachitism is associated with hypo-thyroidism; in these cases the general nutrition improves and growth recommences.

Others have suspected a relation between the pituitary gland and rachitism. The physiological importance of the pituitary gland has been much studied, first by physiologist, then by clinicians. Extirpation of the pituitary gland, especially in young animals, causes arrest of development and disturbances of dentition, the osseous system, and metabolism. It appears that the action of pituitary extract consists in improving the utilisation of the mineral salts which reinforce the organism, and in diminishing their elimination. Pituitary extract may stimulate these processes in rachitic patients, granting that hypo-function of the pituitary gland exists in them.

All the organs of internal secretion represent so many forces linked together in a long and intricate chain which governs the formative and protective rhythm of the organism. Thus it may be believed that rachitism has a polyglandular pathogeny.—(*La Clinica Veterinaria*).

## THE WORK OF THE BRITISH ARMY VETERINARY CORPS AT THE FRONTS.

By Maj.-Gen. Sir FREDK. SMITH, K.C.M.G., C.B., F.R.C.V.S.  
(Reprinted from the *Journal of the Royal Society of Arts*),

(Continued from p. 276).

It will be evident to you that horsemastership in the present war has left much to be desired, through the pardonable ignorance of those in charge. Officers and men without the most elementary acquaintance with horses in civil life, have found themselves responsible for the care and management of a strange and capricious animal. Among the many difficulties of the new army there was none that it had to face greater than this; it is a subject in which information could not be obtained by any other means than that of practical experience. Nearly all the painful and frequently fatal diseases of the digestive system of the horse are due to errors in watering, feeding and work. The principles governing health and efficiency are hard and fast, there is no compromise, though under the conditions of active service much may have to be done which we know to be wrong in practice, but military necessity knows no law.

We must, however, leave the questions of the prevention of disease and injury, and of the promotion of health and efficiency in order to outline the methods of dealing with sick animals in war.

I am now about to tell you how 1300 officers\* and 27,000 soldiers, exclusive of 6000 coloured men, are employed as a corps in the various theatres of war in looking after questions of health and disease as affecting all classes of army animals. Let me remind you that the horse is not the only animal in the service. Though the public thinks in terms of horses, we must not forget that the mule is largely employed, while thousands of oxen and camels are employed in African, Egyptian, and Arabian theatres of war. All these different animals come under the care of the Veterinary Service.

We will begin our study of the question by taking the smallest complete unit of all arms, i.e., the Division.

Every division of our army is provided with a staff, consisting of officers, non-commissioned officers and men of the Royal Army Veterinary Corps. Each veterinary officer of the division has charge of a certain number of animals, and for the carrying out of his duties he is responsible to a senior officer, known as a Deputy Assistant Director of Veterinary Services. This latter officer is in turn responsible to the Assistant Director of Veterinary Services of the corps of which the division forms a part, while the corps officer is responsible to the Deputy Director of Veterinary Services of the army to which it belongs. The Deputy Directors of arms are, in turn, subordinate to the Director of Veterinary Services at General Headquarters. This is the chain of administrative responsibility by which the whole veterinary machinery works, and by which its efforts are directed and co-ordinated. It is the mechanism by which the humblest animal in the force receives veterinary attention from the moment of its being ill or injured, which directs its steps to hospital, and finally returns it to duty. No distinction is made in the matter of solicitude or care between the transport mule and the officer's charger.

Every division possesses a special veterinary organisation known as a Mobile Veterinary Section, the function of which is to form a combined collecting station for the sick, and a field veterinary hospital. It is composed of an officer, non-commissioned officers and men of the Royal Army Veterinary Corps, and is provided with its own

\* Practitioners from every quarter of the Empire volunteered their services.

transport for stores and equipment. Wherever the division goes its mobile veterinary section accompanies it. The advantage of bringing the sick of a division together for treatment is obvious, for not only is a sick animal a clog on the mobility of the battery or regiment to which it belongs, but there is no one to look after it without depleting the fighting strength.

The cases sent to a mobile veterinary section are broadly of two kinds: those which will be fit again in a few days and those requiring prolonged treatment. The governing principle in working a mobile section is that it must evacuate its serious or prolonged cases, in order to continue to perform its function as a collecting station in the field. The location of the mobile section is known throughout the division, it flies a distinguishing flag, and at night distinctive coloured lanterns are displayed. In stationary warfare it is connected up by telephone with the headquarters of the division, and care is taken in selecting its site that suitable accommodation is provided. For example, it is no use locating a mobile veterinary section some distance from a water-supply, or away from a main road.

In mobile warfare the section, in addition to receiving sick, has also to collect any animals abandoned by the division. There are always some which at the last moment are found unable to accompany their units, and these are left behind with the full knowledge that they will not be neglected. When a division is moving, its mobile veterinary section is the last to march off, and time is thus given to collect waifs and strays, and to make a final evacuation of those animals intended for hospital.

Every animal sent to a field veterinary section is accompanied by a form, which gives the name of the unit to which it belongs, the disease from which it is suffering, and a description of the animal for the purpose of identification. On admission this is checked, and the diagnosis verified, and a serial number allotted, which is placed on a label tied to the head-collar. A special coloured label is also tied on, summarising the ascertained facts regarding the cause of inefficiency, a white label being used for medical cases, green for surgical, red for contagious, and blue for casting. In addition each animal bears a stencil mark in paint on the quarter, showing the number of the mobile veterinary section to which it belongs.

A careful examination of all patients received by a veterinary section is of the utmost importance, for it is here that cases of contagious diseases may be caught in their earliest stages. If the system described is followed out, it is known at once to which unit of the division the animal belongs, and notification of the existence of contagious disease is sent it as a warning.

No more important duty exists than the early and thorough examination of the sick, otherwise cases of incurable and highly infectious disease, such as glanders, will be sent back to the base, and mixed up on the way with unaffected horses. Great judgement is also required in deciding which of the ordinary cases may with advantage be retained for treatment, and which should go back to base hospitals. Every animal sent back unnecessarily is a loss to the division, and a source of expense to the State.

What I have just described to you is the first procedure in dealing with sick animals in the front line. The second step is as follows.

When a mobile veterinary section clears out its sick, they are handed over to a formation known as a *Veterinary Evacuating Station*. This is not a divisional unit, but belongs to the corps of which the division forms part. Each corps has one evacuating station, charged with the duty of receiving the sick from all the mobile

veterinary sections, and transmitting them to the base veterinary hospitals. These evacuating stations are fixtures, located near to corps railhead, close to a water-supply and main road, and, if possible, shelter is provided by tents or in billets. The stations fly the usual distinguishing flag, while notice-boards and finger-posts at cross-roads indicate their locality; their position is also published in corps orders.

Every animal forwarded to an evacuating station appears on a roll furnished by the mobile section; this gives the information contained on the coloured label previously spoken of. Labels get lost, and are very often eaten by neighbouring animals; in fact, the problem of field marking for the purpose of identification is not entirely solved at the present time, though more or less ingenious devices have been employed.

The sick in the evacuating stations are capable of being more thoroughly and deliberately inspected than is often possible in a mobile veterinary section. The diagnosis is again checked, and a rigid search is made for contagious and infectious diseases, as it is most important that they should not escape undetected from an army area. So important is this that a certificate has to be rendered to corps headquarters specifying that each animal admitted to the evacuating station has been inspected, and stating the result. This inspection is a part of the sifting which began in the mobile section and which terminates, as we shall see, only when the animal is again fit for duty. It is the essence of veterinary supervision, and nothing can replace it. Every case passing through an evacuating station, together with its disposal, is entered in a book, and from this, totals are supplied at the end of the week to the corps headquarters concerned.

The sick are sent to the base by the evacuating stations two or three times a week, empty supply trains being utilised, or a special sick horse train made up. A train load is usually 280 horses, carried in thirty-five trucks. On no account is the evacuating station allowed to become congested, otherwise its functions are impaired, and above all there is a delay in getting the more serious cases under treatment. In some places evacuation may be carried out by water transport, and if the distance is not considerable suitable cases may march by road. Prior to evacuation all surgical cases are dressed, and first-aid dressings accompany the party. The surgical and medical cases travel in their groups, and the contagious cases travel in trucks on which is marked the instruction "To be disinfected." One attendant is told off to every two trucks; forage and a good supply of drinking water go with the animals; every evacuating station holds on charge large water bags for this purpose. Petrol tins and cartridge containers were at one time employed on these trains, and were found most useful for carrying water. Each evacuating station possesses a motor ambulance, the majority of these being gifts. From all sides one hears of the enormous value of the ambulance service in the present war, especially in France, where it has received its full development. Some hundreds of ambulances are employed in the Veterinary Service, many being motor ambulances, each capable of taking two horses.

The evacuating station having entrained its sick for the base, the operations of the second piece of machinery in the scheme come to an end, and the third takes up the work. These are the hospitals found at, or in the locality of, the various bases established for the armies, each group being told off for a definite portion of the fighting line. A group consists of two, three or more hospitals, viz., a *Reception Hospital*, a *General Hospital*, and a *Mange Hospital*.

(To be concluded.)

# ANGLO-FRANCO-BELGIAN VETERINARY RELIEF FUND.

## BRITISH COMMITTEE.

A meeting of the British Committee of the Fund was held at 10 Red Lion Square, London, on Friday, 10th January, when the following members were present:—Mr. F. W. GARNETT, C.B.E., in the chair; Maj. J. Abson, D.S.O.; Mr. G. A. Banham; Prof. S. H. Gaiger; Messrs. A. Lawson, W. J. Mulvey, T. Salusbury Price, W. Packman, S. H. Slocock; Sir John M'Fadyean; Mr. R. C. Trigger; with Sir Stewart Stockman and Mr. Fred Bullock, Hon. Secretaries.

The minutes of previous meeting, on 22nd Oct., 1915, were read and confirmed.

The Hon. Secretaries reported that, as instructed at the previous meeting, an appeal was drawn up and issued early in 1916 to all Veterinary Associations, and to every member of the profession. Subscriptions as received were acknowledged, and a list was published in the veterinary press from time to time, until the end of 1916, when it was thought advisable not to make any further appeal at that time.

The total amount received to date in subscriptions is £278 8s. 11d., bank interest £27—total £305 8s. 11d. Incidental expenses amount to about £3.

The following translation of a letter from M. Vallée, President of the French Committee, was then read:—

## COMITE ANGLO-AMERICAIN-FRANCO-BELGE DE SECOURS VETERINAIRE.

ALFORT, 23 December, 1918.

Dear Sir,—It will be with feelings of emotion that our Committee will learn of the generous proposals of the British Committee with regard to our common object. Every French Veterinary Surgeon will see therein a new peculiarly touching manifestation of that hearty and active co-operation for which France is so much indebted to your great country. In return we can offer to the British Nation only our assurance of undying gratitude and attachment.

Our Committee is at present preparing a new appeal to all French Veterinary Surgeons for financial assistance. We are also asking, on behalf of our unfortunate members, for books and instruments, and for information as to vacant posts where our poor comrades may be able to support themselves by their work.

At the same time we are inviting those Veterinary Surgeons who are victims of the war to send in their names and to make known their precise needs.

Our assistance must be given forthwith. Germany will obviously have to pay for the devastations due to her hordes, and our own country, too, will give some assistance. But such reparation can only be tardy, and it is now that our help is required.

We have in hand £1200, four hundred pounds having already been expended. Our American confrères are placing at our disposal about £480. With this sum of £1680 we have to help more than 300 members. These figures will suffice to show you what inestimable assistance the generous intervention of your Committee will mean to us. We can never sufficiently express to you our gratitude, and we are deeply touched by your kind intention, which you have communicated to me, of handing over your funds to us for distribution.

Will you kindly accept and convey to the members of the British Committee the assurance of our cordial devotion.

H. VALLÉE.

It was thereupon resolved: "That in view of the pressing needs of the Fund, the sum of £200 be transmitted immediately to the Central Committee for distribution, and that steps be taken to issue at once an

urgent appeal to British Veterinary Surgeons and Veterinary Medical Associations, asking for further contributions."

The form of the appeal was left in the hands of the Honorary Secretaries.

## ANGLO-FRANCO-BELGIAN VETERINARY RELIEF FUND.

A Fund for the relief of Veterinary Surgeons and their families who have suffered through the invasion of Belgium and Northern France, has been established by the French Society of Practical Veterinary Medicine, and a Central Committee has been formed, consisting of representative Veterinary Surgeons in Belgium, France, and England.

There is an Executive Committee of 25 members, of which the President is M. H. Vallée; Vice Presidents, MM. Dechambre and Lavedan; General Secretary, M. H. Rossignol; Assistant Secretary, M. P. Savary; and MM. Asselin and Houzeau, Place de l'école de Médecine, Paris, Honorary Treasurers.

The French Committee is making an urgent appeal for funds, and information as to vacant posts where victims of the war whose homes have been devastated may be able to support themselves by their work.

The British Committee appeals for contributions from British Veterinary Surgeons. More than 300 French and Belgian Veterinary Surgeons are in urgent need. They have lost all—house and goods, and livelihood. All contributions will be handed over to the Central Committee to be distributed by them.

It is earnestly hoped that not only individual members of the profession in this country, but also every Veterinary Society will send donations to the Fund.

Remittances should be made payable to the "Veterinary Relief Fund," and sent to the Hon. Secretaries, 10 Red Lion Square, London, W.C. 1.

## ELECTION ADDRESS.

Gentlemen,—Having been nominated for the next election, as a candidate for the Royal College of Veterinary Surgeons, I place myself before the Profession, as an exponent of the policy stated below. Having nothing to gain, with no axe to grind, votes and support are solicited for the programme laid down.

My statement of policy does not pretend to cover the whole ground, but enough, it is hoped, will be given to clearly indicate the general procedure sought to be followed.

Our profession has never had an opportunity like the present. The nation stands on the threshold of a new era, and the work of reconstruction involved, will throw upon us, and particularly the Council as our governing body, many obligations. These will require us to ask, and insist on our being given a full legal status, and adequate remuneration for all work undertaken. We cannot further accept the position of being non-executive and non-administrative, and we must renounce for all time the subordinate position we are at present placed in, to medical officers of health, sanitary inspectors and policemen.

As a profession we are asked to stand together and through the College, as our mouthpiece, to state to Government Departments and local authorities, the fees at which we are prepared to carry out our duties. No longer must local men be left on their own to fight and struggle with these strong bodies, wrangling over the pittance of fees, which have been doled out, in the past, as remuneration for professional services.

In like manner, such obligatory tests, as the "malfein" for all animals before going into collieries, ought to be

rigidly controlled by the Profession as a whole and the remuneration for same.

Our Council has never contained a fair representation of country practitioners *per se*: nor has the districts into which the country can be divided, been adequately represented. Why should not the Council contain men returned on the following plan:—

R.A.V.C., one; Boards or Depts. of Agriculture, four; London, two. One each: *Areas*—Liverpool and Manchester, Birmingham, Derby and Nottingham, Durham, Sunderland, and Hartlepool, Glasgow, Edinburgh, Belfast, Dublin, Cork; *Counties*—England—Northern, Eastern, Western, Southern; Scotland—Northern, Western, Eastern, Southern; Wales—North, Mid, South; Ireland—North, Mid, East, West, South.

This will give a fair representation to every interest in the profession; will supply men who are in touch with local conditions, and anything arising in an area will be capable of being dealt with by the local representative, whose views and statement of the facts will be of great assistance to the Council.

Our own Bill will, it is hoped, be shortly before Parliament, and probably soon be made law. Its progress through the Houses, especially in Committee, will require very careful watching and handling. If we get the finance portion through, we will be in possession of much needed funds. Our position, from being bankrupt, will be fairly sound and if a strong reserve fund is created will, in a few years be absolutely "A 1 at Lloyds."

Being strong financially the Council will be enabled to extend the scope of its work and take up functions too long in abeyance, such as "Lobbying" in Parliament on all Bills or subjects touching on veterinary work; lobbying at all Breed Societies, Milk Associations, and Meat Trade interests; Government Departments both Home, Colonial, and Dependencies; Local Authorities, etc.

Our Council ought to allocate funds for "Research," so that men adapted for such work would be enabled to carry it on.

Moreover, the payment of actual out-of-pocket expenses of all members of Council attending Council duties is a democratic measure of the first order thereby enabling many capable men to be put up as candidates who are at present debarred on account of the double loss. The present Charter requires revising, and the principle of holding Council meetings in places other than London extended. Although the Council for some inscrutable reason, does not avail itself of the permission to meet once every three years in Edinburgh and Dublin, it would be of great advantage if the Council were compelled to travel about a bit.

The Council's relations to the teaching schools is limited to laying down the curriculum and the holding of the examinations while the questions as to what manner of men are permitted to enter the schools; what facilities for properly educating them when there; the educational qualifications of the men who are there as teachers; and the general facilities for educating men in the higher ethics of life are totally ignored. How can the profession advance and keep its proper place in our social organisation under these conditions? It is easy to see why "Vis unita fortior" is more honoured in the breach.

Such are the views and lines on which I ask for your support. They are framed for the profession, the whole profession and nothing but the profession. Cliques and cabals stand outside my scope and if elected I hope to be able to put enough enthusiasm and time at the work that will stir up the dry bones of Red Lion Square and give the whole of you a real live Council serving your interests. You are seething with discontent. Go where one

will one finds men everywhere grumbling but you are as men without a voice. You are not heard. You are all keenly alive to the many disadvantages under which we labour and you are bazy as to the means and ways of removing the grievances and disabilities under which we are placed. Very many of our grievances and disabilities arise from within ourselves, we have been content to do as we were told; we were disunited, and we have never had a policy laid down from our governing body round which we could have rallied and marched to victory. You know that there are many subjects which at present are better not touched on in print, but which cannot be permitted to continue.

You have the matter in your own hands and if the views expressed above commend themselves to you you will best support them at the ballot by plumping solidly for a pure country practitioner totally unknown personally to the bulk of you but prepared to support policy on the lines laid down.—I have the honour to be,

Yours, etc.,

Llanelly.

JOHN HILL.

#### "ACTINOMYCOSIS IN A MARE, TREATED WITH AUTO-VACCINO-THERAPY."

The article on the above by Mr. Scott, Bridgwater, in *The Record* of January 18th, is very interesting indeed, and I shall be glad if Mr. Scott would supplement it with the following information:—(1) Length of time under treatment; (2) Number of injections given.

The article not being dated, the only guide to these points is that the injections were "administered every seven or nine days," and that after "the seventh and subsequent injections," etc. Taking the intervals to average eight days, and the number of injections to have been ten, the time would appear to have been eighty days.

Bideford, Devon.

WM. ASCOTT, M.R.C.V.S.

Feb. 3rd.

#### THE DEARTH (?) OF PRACTITIONERS.

Dear Sir,—Your leading article headed "Contagious Disease" in *The Veterinary Record* of February 8th.

The statement that it is doubtful whether it is practicable at the present time, owing to the shortage of Veterinary Surgeons, to carry out properly the Tuberculosis Order if it were re-introduced, or to deal effectually with other contagious diseases which are now likely to crop up, will, I think, come as a surprise to some country practitioners. I don't know whether my district, (agricultural) is exceptional, but within a radius of 20 miles of me there are I believe more than a score of Veterinary Surgeons, all in practice, and all good reliable men, with good practices.

Now if there is such a shortage of practitioners in other parts of the country this ought not to be; for there is no doubt we down here travel the same roads as one another daily, and so, in a way, waste a lot of time. However patriotic one might be, one cannot just leave an established practice and go and start all over again in another district which may be without a Veterinary Surgeon. The only remedy to me seems some sort of State control similar to the panel doctor.

I was discussing your article with a neighbouring practitioner yesterday. He had just been to see, as an inspector, a case of Mange reported by a neighbour, and as he said, the other practitioner treats the case and he (the inspector) will call occasionally to see how it is doing—more waste, as he agreed.

Again, I know another veterinary inspector whose duty it is to inspect fairs held right outside the door of

another veterinary inspector five miles away. And so it will be, I suppose, under the Milk Act, unless the local nuisance Inspector does a Veterinary Inspector's duty. Yet we are short of Veterinary Surgeons! If this is so, there are at any rate some unqualified ones coming along. A short time ago a former client of mine showed me a letter from his son, a R.A.V.C. sergeant, in which the writer says he now knows the use and doses of all the drugs; has supplied himself with knives, suture needles, hypodermic syringe, trocar, seton needles, écraseur, etc., and thinks he has got all he will want when he returns to the farm, which he expects to do shortly.

Again, I called recently to see the new tenants of a farm at which I have always attended. I found this new man to be a demobilised R.A.V.C. sergeant. He had a small pharmacy fitted up, and began writing prescriptions which he assured me were specific for certain complaints.

The above two instances in my little circle may give R.A.V.C. Officers who intend to return to country practice food for thought, and make them consider whether it will not be wise for Veterinary Surgeons in the future to be few and far between. Then quack medicine vendors—but I mustn't go on.

One other thing, sir, if you take the practitioners in the 20 miles radius mentioned above, and then look for those same names in the list of the annual subscribers to the R.C.V.S., you will, I think, find them nearly all missing in the latter. If I hadn't written so much I should have liked to have given, in my opinion, one or two reasons why.—Yours faithfully,

10th February.

COUNTRY PRACTITIONER.

### THE PRELIMINARY EXAMS.

To the Editor of "The Veterinary Record."

Sir,—As there has recently been shown so much base ingratitude to the members of the Council of the R.C.V.S.—certain members of the profession making them the object of a criticism as unkind and uncalled for as it is unjust and untrue, one feels a not inconsiderable amount of hesitation in putting pen to paper to express even the slightest disapproval of any action that this body is taking.

However, as nothing but good can come out of honest criticism, and as I feel that there must be many members of the profession holding the same opinion on the question of ex-officers, N.C.Os., and men, who have served in the war, being granted total exemption from the Preliminary Educational Examination, I write to protest against a step which may possibly have no less ill-effect than making still more marked the already existing educational inferiority of the profession, as a whole, when its members are taken *en bloc* and compared with those of any of the learned professions.

One really despairs of ever seeing the profession of Veterinary Science with any other than its present status—socially and intellectually. For many years we have had the "Existing Practitioners," but it would certainly have been within the lifetime of many of the present members of the R.C.V.S. that it could have been said that no one was on the Register who had not passed some sort of an educational test. Now, with one retrogressive sweep by our Council, any such expectations are at once demolished, and we are condemned to continue with names on the Register without any educational guarantee behind them.

At their meeting on the 24th ult., the Council accepted three names on the strength of testimonials from schoolmasters, but I ask, knowing the popular opinion as to how much education is necessary to make a "Vet." can

these testimonials be anything more than mere personal opinions?

And, even those who are employed as teachers at Veterinary Colleges sometimes place a very low estimate on the amount of knowledge necessary to make a Veterinary Surgeon! I remember that just before a Class B examination at one of the Colleges a few keen students approached the Professor of Physiology, and represented that he had omitted to include in his lectures anything on the physiology of the spinal cord. Imagine their surprise when he replied, "Veterinary surgeons don't require to bother about that!"

If this is the view held by an eminent medical man, one can easily forgive an old lady who wrote to a military friend of mine, and requested that he should use his influence to get a job as a "Vet. in the Army" for her coachman, who had just been called up under the Military Service Act!

When taking a personal opinion as to whether an intending student has received sufficient educational training to make it likely that he will eventually make an efficient veterinary surgeon, one must not ignore the prevailing opinion of the general public. What this opinion really is was very well expressed by Maj.-Gen. Sir Frederick Smith, in a paper read last December before the Royal Society of Arts. He mentioned that a certain Roman General, deploring the state of veterinary knowledge in Italy, wrote that the treatment of animal diseases in that country appeared to be regarded as a mean and contemptible occupation. Sir Frederick Smith then proceeded to say that although 1500 years had elapsed since that was written, public opinion had undergone very little change in this respect. I think that these references should suffice to show how dangerous it must be to allow schoolmasters' certificates to be taken as sufficient evidence that certain intending students may be regarded as having sufficient educational knowledge to entitle them to exemption from any form of educational test prior to their presenting themselves for their professional examination.

Although those applicants for exemption have certain claims on their country, I do not think that these should be met at the expense of any profession.

I, myself, returned from the Boer War to find that I had to recommence Latin, French, Algebra, Euclid, etc., to gain admission to a College, but I managed to pass the examination in some four or five months, and certainly did not think that in having to do this I was being unfairly treated by an ungrateful country.

In taking this step it appears to me that the Council of the R.C.V.S. has shown more sentiment than reason; and if I were asked for a definition of sentiment, I should say: Sentiment is that emotion which sometimes guides, and even appears to justify, thoughts and actions against better judgment.

One can only regret that at the same Council meeting an application for admission to the examinations for the diploma of M.R.C.V.S., made by a lady who could probably produce most satisfactory educational qualifications, was refused on the ground that the College does not possess the power to admit women to the examinations for membership.

If it has the power to sweep away the entrance examination, the sooner it acquires to itself this other, more desirable power, the better it will be for the profession.

Some day the veterinary profession will take its place on an equal plane with the learned professions, but that will not be until forty years have elapsed after the institution of a preliminary educational examination of the same standard as those required by the learned professions, followed by a College course of five years, instead of the present four.

Yes, this reform will come in response to the unanimous call of the whole profession, as soon as it realises

that herein lies the remedy for that state of affairs whereby a Medical Officer of Health has a salary of £800 a year, and the Veterinary Officer is placed under his supervision and given a mere £200 for his whole-time services.

And, that this is the remedy, is because it strikes right at the very root of the cause—*inferior education*.

Yours faithfully,  
with B.E.F.

### ARMY VETERINARY SERVICE

#### ORDER OF THE BRITISH EMPIRE.

The King has been pleased to give orders for the following appointments to the Most Excellent Order of the British Empire, for valuable services rendered in connexion with Military Operations in East Africa, dated Jan. 1, 1919:—

O.B.E. (Military Division).

Capt. A. M. HOWIE, S. African Vety. Corps.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Feb. 7.

REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Temp. Capt. W. Sherriff to be actg. Maj. whilst holding the appt. of D.A.D.V.S. (July 28, 1918).

Feb. 8.  
Temp. Lts. to be temp. Capts.:—W. F. Aston (Jan. 8);  
L. P. Weidenbach (Jan. 26).

Feb. 10.  
Temp. Capts. relinquish their commns. (Feb. 11), and retain the rank of Capt.:—R. J. Hall, on acct. of ill-health; J. Gosling, on acct. of ill-health contracted on active service.

Feb. 11.  
Temp. Capt. G. S. Walker relinquishes his commn. on acct. of ill-health (Feb. 12), and retains the rank of Capt.

Temp. Lt. to be Capt.:—C. J. Peach (Jan. 25).

Feb. 12.  
Temp. Lts. to be temp. Capts.:—J. Craig (Nov. 12, 1918);  
C. E. McCrea (Jan. 15).

To be temp. Lt.:—C. Macpherson, late temp. Lt. R.A.S.C. (Jan. 27).

Temp. Qrmr. and Lt. W. G. Thornton, R.A.V.C., to be Capt., under Art. 320, R. Wt., for pay and promotion (July 29, 1918).

### OBITUARY.

WILLIAM BEAL, Thrapstone, Northamptonshire.  
"Existing Practitioner."

Mr. Beal died 13th Jan., Aged 64.

*Several communications are unavoidably held over.*

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1598.

FEBRUARY 22, 1919.

VOL. XXXI.

## TWO IMPORTED DISEASES.

The Board of Agriculture has recently issued to the practising veterinarians of Great Britain two circulars, dealing respectively with rabies and foot-and-mouth disease. Both emphasise the greatly increased danger of importing disease in which the country now stands, and ask practitioners to be constantly on the watch for cases that are even suggestive. This is especially urgently worded as regards foot-and-mouth disease; for we are asked "to notify every case that is in the slightest degree suspicious, should you find yourself unable to say definitely that disease does not exist." This may lead to false alarms, which the Board evidently accept—for the sake of lessening the risks.

The procedure on the part of the Board is not usual, but the whole profession will see the justice of this call for co-operation. At any moment the question of whether disease does or does not obtain a formidable start may depend upon the alertness of a single practitioner. One clinical error may cost the country thousands of pounds in the case of the one disease, or human life in the case of the other. Remembering this, we cannot be too careful; and our errors should all be on the side of excess of caution.

## "GOING THE WRONG WAY."

Attention has again been drawn to this subject, the importance of which even to-day is perhaps not sufficiently recognised. A generation ago, comparatively few clinicians realised the danger of fluids passing into the trachea; to-day, it is much better understood. In many respiratory troubles the accident is so frequent that it should contra-indicate the use of draughts in such cases; in other conditions, also, it is probably more common than is generally supposed. The degree of danger arising from it is more debatable, and certainly depends a good deal upon circumstances. It is known that the healthy respiratory passages can absorb quantities of water very rapidly, and are also remarkably tolerant of at least some irritants. There is still much to learn as to how far these attributes may be modified by disease, what irritants are the most dangerous, and what non-respiratory affections most predispose to the accident. Mr. Harvey's remarks on the last two points are of value; and, though the subject must cause uncomfortable reflections to many old practitioners, it deserves more discussion than it has yet received.

## THE SHARE OF SUPRA-RENALS IN THE ACTION OF THE PNEUMOGASTRIC UPON THE HEART.

H. Roger contributed an article upon this subject to the *Journal de Physiologie et de Pathologie générale* for 1917. It is known that two antagonistic nerves, the sympathetic and the pneumogastric, act upon the cardiac muscle. The function of the sympathetic being conditioned by the supra-renals. Roger has thought it advisable to study the action of the vagus nerves upon the hearts of animals deprived of their supra-renals. The experiments were performed upon rabbits, and their supra-renals were removed by the abdominal route. Half-an-hour after the termination of the operation, which lasted ten minutes, the carotids of these animals were connected with a mercury manometer. Afterwards, first one and then the other pneumogastric was isolated and divided; or else both were left intact. In this manner a variety of experiments were performed, which led Roger to the following conclusions:—

In animals which have been "decapsulated" (deprived of their supra-renal capsules) section of both vagi produces a slight and transient descent of the arterial pressure; but as the normal excitant action of the sympathetic is not present, a secondary elevation of the pressure is not produced.

When the peripheral end of a pneumogastric of a decapsulated animal is faradised, cardiac paralyses are obtained which are longer at each successive stimulation, and which may reach a duration of thirty-seven seconds.

In the normal animal, successive excitations of the vagus produce diastolic depressions, each feebler and shorter than the last. These modifications of force and duration do not appear to be due to an exhaustion of the nerve. They probably depend upon an intervention of the supra-renals; because, if a dilute solution of adrenalin is injected into the veins of a decapsulated rabbit, it is found that the cardiac reactions recover the normal type, and, as the injection is prolonged, the influence of the pneumogastric is lessened till it almost disappears.

The intervention of the supra-renals also explains why successive excitations of the pneumogastric are followed by a secondary elevation of blood pressure in intact animals, and by a descent in decapsulated ones.

In the course of experiments upon decapsulated animals it is frequently seen that excitations of the pneumogastric, after having produced extremely long paralytic periods of the heart, cause others of no more than the usual duration. This return to the normal is especially observed when the animal has been left for some minutes to recover. It may

perhaps be attributable to a functional modification of the myocardium, or perhaps to a vicarious intervention of the diverse paraganglia.

In decapsulated animals, both pneumogastrics of which have been cut, the excitation of the peripheral end of one of the cut nerves determines, at the same time as the paralysis of the heart, a definite paralysis of the respiration. These animals may be restored to life by successively injecting adrenalin intravenously and practising artificial respiration.—(*Revista de Higiene y Sanidad Pecuarias.*)

W. R. C.

### THE WORK OF THE BRITISH ARMY VETERINARY CORPS AT THE FRONTS.

By Maj.-Gen. Sir FREDK. SMITH, K.C.M.G., C.B., F.R.C.V.S.  
(Reprinted from the *Journal of the Royal Society of Arts*).  
(Continued from p. 284).

When the train arrives at the *Reception Hospital* the cases are taken to the admission section, where the serial numbers, descriptions, and diseases are verified. Here they are marked for retention, transfer, or disposal, after being grouped into surgical, medical, contagious diseases, mange, etc. The reception hospitals retain nothing except very serious or slight cases—the former being unfit to be moved, and the latter likely to be so short a time under treatment that it is economical to hold them. These reception hospitals have to be prepared to deal with two or three days' admissions, and are generally for 500 to 750 cases. During their stay in reception hospital, the animals are tested by what is known as the mallein test, to ascertain whether they are free from glanders, so that forty-eight hours are spent here; this time is occupied in grouping the sick and attending to their immediate requirements. All animals that pass the test for glanders can now be disposed of by transfer to the other branches of the base hospital system. This is carried out by the *Transfer* section of the reception hospital, which takes over the various surgical, medical and mange groups. From these groups cases are drafted to the general and mange hospitals in any number desired, the available accommodation at each hospital being previously known.

The *Disposal* section of the reception hospital deals with the cases for destruction or sale, the latter being handed over to the Remount Department.

A "treatment card" for each patient accompanies it wherever it goes, so that any change in diagnosis, or the development of a new disease may be noted. The card explains what the patient is unable to express, and is also a complete record of the animal while under treatment; further, it indicates how long any case has been in hospital, for there is a time limit, generally placed at three months, beyond which it is not economical to retain an animal.

We must now look at the *General Hospital*.

These are designed for 2000 cases, and are generally divided into eight sections or sub-divisions, each being told off for a certain class of case—for example, lameness, surgical foot cases, other surgical cases, pneumonia and catarrh, debility, contagious diseases other than mange, etc. No case of mange is admitted to a general hospital; should one occur, it is transferred to a mange hospital. On arrival at a general hospital the cases are verified from their treatment cards, and posted to their proper wards. It is evident that the experience gained by officers in their special class of case is unique, and their expert opinion of the utmost value to the patient.

As an animal in any of the hospital wards becomes convalescent, it is told off to a definite portion of its own ward for special feeding and exercise, with the object of getting it fit for work, and twice a week the cured cases in each ward are sent to the *Discharge* section of the hospital. Here the animal receives an increase in food and exercise, and when quite fit for work is again tested for glanders; if passed free it is transferred to the nearest remount depot for issue to the troops.

Cases of debility take a long time to recover, and for these special *Convalescent* depots exist, where the animals are at liberty in the open during the day, and housed at night. Some of these convalescent depots occupy a large tract of country; one of nearly 3,000 acres, was the first chosen, and held 4,000 animals. The large majority of these during the summer are left out day and night, only the weaker animals being housed. During the winter the numbers in a depot are reduced, and all the animals housed. The principle of construction employed in these depots is to have a series of well-fenced enclosures, each with its own buildings and water-supply, with facilities for inspection, exercise, watering and feeding; each group has its own exercising ground. The object of this system of separation is to prevent extension of contagious diseases should any appear, and, to make doubly sure, each group is subdivided into smaller groups of fifty horses. This not only gives additional isolation but secures individual attention. It is very easy to overlook a case in a mob of 1,000 animals; it is practically impossible when the group is reduced to fifty.

You may, perhaps, be surprised at the care which is paid to the isolation of the horses into small groups, but you will remember that the animals in these convalescent depots are allowed their freedom, and in consequence mix with each other. The horse is the most sociable of animals when with his fellows; he has his friends whom he nibbles and rubs against, and also his enemies whom, if he is the weaker, he avoids. In spite of the systematic inspections which have been carried out before he gains admission to a convalescent depot, he may nevertheless, be harbouring infectious disease in a hidden form, which later becoming developed will certainly infect the other animals in the group. Should such a case occur, the risk of infection is reduced to relatively unimportant numbers by the system of small groups. In this way infection of convalescent depots is prevented or controlled. The rule, however, for preventing infection is that no animals are sent there except those requiring a rest owing to debility and exhaustion; no case of disease, and nothing requiring active treatment is ever knowingly admitted.

On arrival at a convalescent depot each animal is carefully examined in order to see that it fulfils the required conditions; those refused admission are returned to their hospitals. The serial numbers are verified, hind shoes removed to prevent damage from kicking, and the whole party remains in isolation for fourteen days, during which time it is given the full benefit of the depot system of nursing. At the end of this period the animals are passed out of the isolation block, and classified according to condition and strength; the weaker ones being kept together. This not only ensures the necessary quietude and rest, but a better distribution of food, for the strong horse will always rob the weak. Horses are very human in some of their characteristics. The diet is most carefully regulated, because an exhausted horse cannot digest whole or raw grain.

As the animals improve in condition they are gradually promoted to the block dealing with those being got ready for discharge; here the feeding is more liberal, and the exercise increased. From this group animals are selected once or twice a week for issue to remount depots, all being tested for glanders before being sent away.

These convalescent depots are organised on the principle that horses at liberty can do a great deal for themselves where proper arrangements exist; for instance, the exercise is carried out on a large semi-circular track which communicates with each enclosure, so that the fifty horses are exercised together, not by being ridden, but by trotting or cantering around with no weight on their backs, as you will presently see on the screen. The pace is regulated by one or two mounted men. Having completed their exercise, the fifty are returned to their own enclosure, and the next batch taken out. It will be obvious to you what a saving in labour is effected by such a system.

There is no part of the method of restoring war-worn animals which more requires a thorough and perfect system than a convalescent depot. Non-recognition of this in previous campaigns has been productive of enormous losses by the spread of disease. Not the least of the triumphs of the Veterinary Service in war has been its organisation and management of convalescent depots.

*Mange Hospitals*, as their name implies, are distinct institutions for the treatment of the highly contagious disease known as mange. It may or may not be known to you that mange is due to a special variety of insect or mite, of which there are two serious types in the horse. One lives on the surface, the other in the depth of the skin. The disease caused by the latter is infinitely more difficult to cure.

In the organisation of a mange hospital the group system is, as usual, adopted. The animals on admission are first classified according to whether they are suffering from the ravages of the surface parasite, or those of the deep-seated one. They are next grouped according to severity, all cases of equal intensity being kept together.

The first important point to decide on admission is the type of disease. This is settled by the use of the microscope. Every case has to go through this routine, and as diagnosed it is sent to its proper ward. If, in addition to mange, the animal is suffering from surgical trouble or other form of disease, it is grouped accordingly, so that the two distinct conditions may be simultaneously dealt with.

The routine treatment of mange may interest you. The cases are first clipped, either by hand or power-driven clippers. The body is then washed to get rid of dirt and such like, and finally the animal enters a swimming bath containing an agent which kills the parasite. The bath may strike you as a difficult measure to adopt, but it is far otherwise. A bath is made by digging a narrow trench to a certain depth, rendering its sides and bottom water-tight with cement, and arranging it so that the animals enter at one end, are completely immersed, and swim the length of the bath to the outlet, which is provided with a ramp, up which they walk to a dripping pen. Here the surplus material is removed, and the patients walk about until dry. Two, three or more baths may be needed to ensure cure, for though the insects may be killed, the eggs they lay are very resistant, and will hatch out later and re-infect the host. We know that a few days suffices for the hatching out, so that the bath is repeated until the skin is no longer itchy, and the new coat is seen to be growing on the bare surface.

The bath is not the only method employed in treating cases of mange; sulphur fumigations are used, and the French authorities have largely adopted this method. It requires the construction of special stabling, for the animals must be so placed that they do not breathe the gas. The head of each projects from the fumigating chamber, and a padding around the head prevents the leakage of gas. The whole surface of the body is exposed to the fumigation for half an hour.

Vapour baths are also employed, not only with the object of getting the animal's body clean, but also to facilitate the penetration of the subsequent dressing. Incidentally it may be mentioned that the boiler furnishing the vapour bath also supplies steam to the swimming bath, so that in winter the animals enter warm instead of cold water.

We have previously seen the system of grouping mange cases according to their nature and severity; they are also grouped in the ward according to the progress of the case. Beginning at the bottom of the stable, they gradually work up as they improve, until they reach the top, by which time it is hoped they are cured. Here they remain fourteen days under observation, any showing signs of itchiness being sent back for further treatment. Those showing no further signs of being itchy are drafted to the discharge section of the hospital, where they remain under further observation until considered safe for issue. During the whole time they are under treatment the patients are liberally fed, without which recovery would be greatly delayed; they are also exercised daily on the automatic system.

Mange is the chief animal plague of active service; it was not always so. Glanders at one time held the predominant position, but applied science has reduced the ravages of this disease to almost a negligible quantity, and we are no longer harrassed by its existence and persistent spread. Far otherwise with mange; we do not know the life-history of the insect apart from the host. We know how the disease spreads, and that in three months a pair of insects can give rise to one and a half million descendants, but we do not know how it is that animals sent into the field, absolutely free from mange and never during their service having been in contact with the disease, may contract it under the conditions of war. The same remarks apply to lice, both in animals and man. No amount of dirt by itself can lead to the production of a living insect, or any other living matter; life can only spring from pre-existing life.

I must, however, leave the subject of mange to conclude the account of veterinary hospitals.

The public conception of these would probably be represented by groups of tumble-down buildings, reposing in winter in a sea of mud, and surrounded by fetid manure heaps, the sick being overcrowded in dark stuffy stables, unventilated and undrained, such as the majority of the working animals in civil life in this country have to endure. The real picture is very different, and shows well laid-out blocks of stabling, comfortable, ventilated and drained. There is no sign of a manure heap, for in this place the highest degree of sanitation is observed.

Well-made roads intersect the buildings, grass lawns exist between the blocks, flower gardens are encouraged, the whole place giving the impression of comfort and civilisation.

These hospitals are the pink of neatness and scrupulous cleanliness, of order, system and method. The watering and feeding arrangements are as perfect as modern science can render them, the whole of the food being prepared by machinery. A system of competition and healthy rivalry is encouraged between the various hospitals to ensure that the highest possible standard is obtained. There are always original and progressive men to be found in every large community, and specially selected veterinary officers are placed in command of our hospitals with a free hand to improve, and instructions never to think that finality has been reached. In one hospital in France the very chains which tie up the horses shine like silver; none of it is hand labour; the chains go into a rotating vessel every day and polish themselves, and the motive power which cuts the chaff and crushes the corn burnishes the chains. In another hospital advantage has been taken of a supply of marsh gas from a large disused manure-pit; pipes are driven

deeply down into the vegetable mass, and the gas led to the hospital, where it is lighted and boils the food for the sick, which thus costs not a penny for fuel. If the animals are so well looked after, you can imagine the care taken of the men, and the comfortable conditions in which they live. They have their flower and vegetable gardens, recreation-rooms and library, and at least one hospital has a band. Far better work is obtained from men when they are well cared for.

Wherever we look in the various theatres of war—France, Italy, Egypt, Salonica, Mesopotamia, or East or South-West Africa, the veterinary hospitals are on a sure foundation. They are modified to meet local conditions and requirements, also climatic needs, but the same principles are observed—system, organisation, and whole-hearted devotion being the watchwords.

(To be concluded.)

#### SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919:—

(In each case the amount subscribed is £1 1s., except where otherwise indicated.)

E. J. Bolton, Athlone	P. T. Lindsay, Maj. R.A.V.C.
W. A. Campbell, Boroughbridge	W. A. Macgregor, Capt. R.A.V.C.

#### THE CONTROL OF CONTAGIOUS DISEASES OF ANIMALS.

Sir,—I think that perhaps your article on the difficulties attending the carrying-out of the provisions of the Acts relative to the Contagious Diseases of Animals would have been more convincing if, besides your reference to the present paucity of veterinary surgeons as a main cause of those difficulties, you had alluded to letters which have recently appeared in *The Record* calling attention to the little use that the authorities make of the veterinary surgeons who are still in practice.

If a client living a couple of miles from my house calls me, say, to a sick pig, and after examination I advise him that he ought to communicate with the police, a veterinary surgeon arrives from Sawbridge-worth (14 miles away) to do the necessary selection and forwarding of the "innards." If the practitioner has on the same day a similar call 14 miles in the other direction, and has his private practice to attend to as well, he will be kept busy.

I will give an example of how this sort of thing works. Some years ago, I received a wire to go to a farm, and some time after I had started another telegram was delivered instructing me not to come, as the cow was dead. When I got to the farm I was shown the carcass of a cow, just dead, lying in a shed beside the highway. The owner had gone to market, but the foreman told me that a butcher had been sent for to dress the carcass. The case suggested anthrax, and I told the foreman that the butcher must not interfere with the carcass until my return; and taking an ear from the animal I went home, and on examining the blood found that the cow had died from anthrax. I immediately returned and ordered the case to be reported to the police. Next day the authorities arrived, specimens were taken and sent to London for examination, and it was not until the third, or I believe fourth, day after the animal's death that the carcass was removed from the shed, dragged along the road to a field, and buried. Severe restrictions were of course put on the place for some time, and as one may imagine, the farmer was greatly indebted to me for my interference and for my promptitude in responding to his telegram. Had I delayed a little and got his second wire the probabilities are that the butcher would have noticed that there was

something wrong and refused to dress the carcass, and it would have gone to the knacker the same day; and, to the farmer at any rate, this appeared to be quite as safe a procedure as the one adopted.—Your truly,

Enfield.

W. R. DAVIS, M.R.C.V.S.

P.S. May I remark that all who write to you on this subject refuse to sign their names. Why?

#### IMPORTANT TO THE PROFESSION.

Sir.—Recently I made application to the several Committees of our Town Council—Watch, Sanitary, Highways—for an increase of pay, pointing out the high cost of living, etc. Result—Salary for Inspectorship doubled; inspection of cows 50% rise; contract with horses 50% rise. I trust all Inspectors will do, or are doing, likewise. It has been said that we are a modest profession (a very fine virtue) in the sense, I take it, that we do not press things enough—hide our light under bushels—and I fear there is something in it. Members of Urban Councils taking all in all hardly know what modesty means, altho' the majority are a fair and reasonable lot of men. But things must be explained to them.—Yours etc.,

The Gables, Reigate,  
Feb. 18th.

CHAS. A. SQUAIR.

Sir,—I am very pleased to see Capt. J. Hill's spirited address in to-day's *Record*. Under present conditions the profession must of necessity be teeming with discontent—Unity is absent, and as a result we are forced to act in a most humiliating way and it is extraordinary how practitioners manage to live on present fees at all.

As an example I may quote the remuneration (!) allowed by one local authority in this district—mileage 1/6 per mile after first 2 miles (one way only.) Inspection of flock of sheep re sheep scab—microscopical exam. reports to Board of Agriculture, etc 5/-! One can imagine what the miner and others would do if offered such a fee, and any other profession would of course absolutely refuse to act in ours: one protests in vain. With the return of the Tuberculosis Order and the advent of the Milk and Dairies Bill it really is essential that something should be done to put us on a fair footing. The medical profession is in reality one of the strongest Trade Unions in existence—why cannot we take similar action.

With regard to private practice—it is hopeless for members to charge proper professional fees in accordance with present conditions if more uniformity does not exist—why cannot a scale of fees be drawn up as in the case of Solicitors. At present it is chaos.

Yours etc.,

16/2/19.

PRACTITIONER.

[What the practitioners in Kent achieved in the matter of C.C. fees is not yet ancient history; and the action of the men in Derbyshire is only a few weeks old. On the next—possibly on the same page, we print the note of Mr. C. A. Squair on the same subject—in a very different tone. It looks as though this correspondent lacks "guts," as they put it in the R.A.F.].

#### DEARTH OF VETERINARY SURGEONS.

Dear Sir,—Your editorial article in *The Veterinary Record*, of February 8th, in which you state that it is impossible to treat with the Tuberculosis Order and other contagious diseases at the present time owing to the shortage of Veterinary Surgeons. I fear that you

have been sadly misled. I quite agree with Country Practitioner's letter in this week's *Veterinary Record*. He states, that within a radius of 20 miles there are a score of Veterinary Surgeons—all in practice. I have a country practice, and within a radius of 9 miles we have 3 Veterinary Surgeons—capable men; but we have never been approached by the Board of Agriculture to do any work for them. What is the reason? They must think we are a lot of children and they can do what they like with us. The time has arrived when a stop must be put to this treatment, otherwise it will be the ruin of the veterinary profession.

Mr. Editor—do you think it fair that the Board of Agriculture should have the power to appoint a certain Veterinary Surgeon in a certain district—to carry out the Contagious Diseases Act when other Veterinary Surgeons are in practice? When one has a good practice, and the clients have every confidence in him, should a contagious disease break out you have no alternative but your opponent is called in and carries out the business, and you have no say in the matter. It is not the remuneration, but it is the unprofessional, degrading and humiliation of it.

At a veterinary medical meeting reported in *The Veterinary Record* of August 26th, 1911, this question was brought up by Mr. Gold, who said it was a great hardship to a local practitioner for a man to be appointed as Veterinary Inspector to operate in the same district covered by another man's practice.

Mr. Stockman (as he was then) said he might not like it himself, but surely someone must be responsible, and unless they were prepared to adopt the only alternative—to appoint every man an inspector in his own practice—the present system of appointing certain men for certain districts must continue; and he did not think it practicable to appoint every man an inspector in his practice (this is what is done in the medical profession. Why not in the veterinary profession?) because however anxious a man might be to do his duty, when the interest of the public clashed with the interest of your clients there was just the probability that the public interest might suffer. I fail to see this argument. I am of opinion that it is the other way about—the inspector who is your opponent comes to your client and makes himself most agreeable, and might strain a point or two in his favour with the object of getting his work. I have heard of it being done. We must be on the same footing as the medical profession—when a doctor has a patient with a contagious or infectious disease. The Medical Officer of Health does not step in and take the case out of his hands, or even go to see the patient. I should like to hear the opinion of some of the gentlemen who are putting up for the Council of the R.C.V.S.

A NON-SUBSCRIBER  
to the Royal College of Veterinary Surgeons.

#### TEACHERS AS COUNCILMEN.

To the Editor of "*The Veterinary Record*."

Dear Sir,—Your footnote to my former letter stating that, "it does little to elucidate the main question, upon which there is a distinct difference of opinion—Is it desirable that the teaching colleges should be represented on our Council Board?" compels me to again ask the hospitality of your columns.

The whole object of my letter was to deprecate what I held to be, the wholly pernicious and schismatic doctrine, that teachers are more highly qualified to hold office in our Council than other practitioners.

It is beyond question that a number of the profession are not satisfied with the Council; the general opinion

is that it is not so much that they have done things which they ought not, as that they have left undone things which they ought to have done.

I have never heard a word of criticism against the individual members of the Council, but as a corporate body the Council is adversely criticised, and in the words of Macaulay, "Surely the uniformity of the phenomenon indicates a corresponding uniformity in the cause."

Anyone glancing at the composition of the Council for this cause, is immediately struck by the large number of teachers thereon, and naturally the following questions suggest themselves:—

(1) Are the teaching schools over-represented? A simple sum in proportion, having for its terms the number of teachers in the profession and in the Council compared with the total strength of the profession shows that they are overwhelmingly so.

(2) Should the schools be represented on the Council? This is very debatable, but as the schools are now, or should be component parts of the Universities, and not the private property of colleagues whose "practice" takes the form of owning a school, there is not the same powerful case for their representation as formerly. The Council, as a Council, should be able to look after the interests of the teachers and students as a whole, and without bias regarding any one particular school.

(3) Are teachers more highly qualified as Councillors than other members of the profession? As a general question the answer to this cannot be definitely given Yes or No, without leading to interminable and profitless argument. The only proof of qualification is performance, and he who renders greatest service on the Council is obviously best qualified, whether he be teacher or otherwise.

(4) Does the Council govern the schools, or do the school representatives govern the Council? That is a question which I leave your readers to answer for themselves.

The popular belief in the profession is, that the Council (like the profession at large), suffers under the incubus of apathy, and that its most discernable policy is that of "wait and see."

I am, Sir, yours faithfully,

A. B. MATTINSON, Major R.A.V.C.

Woolwich, S.E. 18. 12/2/19.

[We suggest the following reflections anent our correspondent's four questions. (1) Calculations of the numbers of teachers in the Council and in the profession are of value only if we adopt the view that teachers come upon the Council as school representatives and nothing more. (2) Universities, whatever powers they may gain over teachers and schools, have no control whatever over the R.C.V.S. curriculum and examinations. (3) We agree that this question might lead to "interminable and profitless argument," and also that "the only proof of qualification is performance." We simply said, and still maintain, that a fairly broad-minded teacher has much better opportunities of fitting himself for Council service than most practitioners. (4) Those who answer this question by saying that teachers rule the Council must face the fact that they never have anything like a majority upon it, with the unavoidable inference that teachers generally make the most effective Councillors.—Ed.]

#### CUMBERLAND PRACTITIONERS AND THEIR FEES.

For some time past a movement has been on foot to combine the veterinary surgeons in Cumberland and to revise and make more uniform their professional charges. The proposal has been to include in this scheme the areas of Carlisle, Brampton, Alston, Penrith,

Wigton, Abbey Town, Aspatria, Ireby, Keswick, Cockermouth, Brigham, Workington, Whitehaven, and Millom, each of which in normal times carries one or more practitioners.

A meeting, having this object, was held at Aspatria, convened by the following circular:—

"Dear Sir,—As the proposals for standardising and equalising the professional fees charged throughout the county, drafted and sent round by Mr. Thompson, did not prove acceptable, and were generally thought not to go far enough, a revised scheme has been prepared on an extended scale and more in the spirit of the replies received. It is now proposed to submit this revised scheme to a meeting of the county practitioners at the "Sun Hotel," Aspatria, on Friday, January 31st inst., at 3 p.m. sharp, at which your presence is requested.

In the event of your inability or disinclination to be present, you are asked to signify the same, either to Mr. Thompson, Aspatria, or to the Convener of this meeting. In the absence of any reply from you, it will be taken to mean that you do not acquiesce in the movement and do not wish to associate yourself with it in any way.

The following gentlemen have already, provisionally, approved the scheme, and it is confidently anticipated that a large majority, if not all the county practitioners, will hereafter fall into line:—

J. Soulsby, Cockermouth,	W. Litt, Whitehaven.
H. Barrow, Ireby,	H. Thompson, Aspatria,
James Bell, Carlisle,	F. Ashley, Dalston,
and J. Donald, Wigton (Convener of the meeting).	

J. DONALD, Wigton."

The following gentlemen attended: J. Soulsby, Cockermouth; H. Thompson, Aspatria; F. Ashley, Dalston; J. G. Bell, Carlisle; J. Trougher, Workington; H. Barrow, Ireby, and J. Donald, Wigton. Apologies for non-attendance and expressing sympathy with the objects of the meeting were received from Messrs. Craig Robinson, Carlisle; T. W. Hewetson, Brampton; Wm. Litt, Whitehaven. No reply was received from Messrs. Steel, Wigton; Little, Alston; Hewson, Carlisle, or Hodgson, Brigham, and by the terms of the circular it was concluded that they did not wish or intend joining the scheme.

Mr. Thompson, who was voted to the chair, said that almost every section of the community were now combined together to protect their own particular interests. The farmers had their Union to look after their interests and he thought it was time the veterinary profession did something in that line also. It was everywhere acknowledged that the veterinary surgeon was very inadequately paid for some of his services, and it was worthy of note that those veterinary surgeons in the county who run shoeing forges along with their practice had some time ago combined with the farriers to raise their prices.

The object of this movement was not intended as a war-time expedient, but is an attempt to federate the members and adopt measures that will secure for us fair treatment and what may be considered reasonable remuneration for our services and charges for the drugs, etc., supplied under normal and settled conditions of practice. We are out to bury the past and redeem the future, and what is most needed is some plan for equalising the charges in the different county areas, as also of adjoining practices—some system of protecting us against ourselves, if he might so put it.

The adherence of 9 out of the 13 qualified practitioners at present in the county is, he considered, a very satisfactory start, which, combined with the measure of support promised by those members who are now serving with His Majesty's Forces on their return home, augured well for the ultimate success of the scheme.

He would ask Mr. Donald to give an outline of the proposals which it was intended to submit to the consideration of the meeting as a basis for discussion :

*A set of Rules for regulating the conduct of practitioners to one another, etc., who become members of this proposed Federation.*

Under this head the following code of ethics was unanimously agreed to :—

1. No solicitation of other people's clients permissible.
2. No undercutting below the scale adopted.
3. When a new client presents himself that is either known, or is reasonably suspected to be the client of another federated member, the reason for the change is to be ascertained, and the preceding practitioner shall be notified by the client that his services are no longer required before the succeeding practitioner takes over the case. The succeeding practitioner will further be expected to privately notify his brother member that he has been requested to attend there, and that he has undertaken the duty or consented on above understanding.

Where another member is in attendance no such case shall be taken on except as a consultation, unless this rule of notification has first been observed.

4. In the event of an emergency call to another's client the case to be handed over to the regular attendant as soon as he is available, and the costs of such attendance to be sent through the regular attendant.

5. Every neighbouring practitioner shall be expected to render all reasonable assistance in case of illness or unavoidable absence.

6. Consultations. Consultants will be expected to first explain their views to the attendant practitioner, and to agree with him how the position is to be put before the client.

7. Subscribers to this scheme are to be held to bind their assistants to a strict observance of its conditions.

8. Each subscriber to this scheme must agree that in the event of any complaint against his conduct, the matter shall be submitted for adjudication to a neutral referee elected by the other members, and that he will abide by the decision of such tribunal.

NOTE. These rules are only to operate as between subscribers to this scheme. Freedom of action and practice are allowed in dealing with competitors who are not, or have not joined in this combine.

*The Food Production Department's Panel System.* At this stage the meeting had before it the panel system of the F.P.D. for the employment of Veterinary services. It was unanimously agreed that (notwithstanding the official intimation that 90 per cent. of the veterinary surgeons to whom these appointments had been offered had accepted them without demur), the members have nothing to do with their scheme, feeling that the terms and conditions offered were little less than an insult to the profession. It was decided that no one holding this appointment shall be admitted a member of this Federation.

It was incidentally mentioned that the Penrith branch of the Agricultural Union had already been employing a layman to do some veterinary work for them, and it might reasonably be expected that the local branches would next be approaching veterinary surgeons to do the work of their members on the basis of the F.P.D. Panel system, or some similar scale.

*The adoption of a general scale of visiting charges on the basis of the mileage one way.*

After discussion of the subject from various points of view and a free exchange of opinion, it was decided the best course was to fix a *minimum* scale, below which no member would need to go in any case, and under which it would not pay non-federated members to try to under-

cut : leaving members free to charge anything above that scale that they might feel themselves entitled to, or their circumstances warrant. A scale of fees was drawn up on these lines and adopted.

*The adoption of a scale of fees adaptable to the requirements of general practice that are considered as fair between clients and ourselves for the services rendered.*

Under this head a schedule of fees was fixed for :—examinations as to soundness : operations (detailed list) : consultations : castration (all species and ages) : parturition and the various conditions arising in obstetrical practice : treatment—by inoculation, by fumigation, by injection, etc. Sanitary, County Council, and Board of Agriculture work : application of the tuberculin test, and the use of tuberculin, mallein, etc., for diagnostic purposes. Post-mortems. A scale recommended to be charged for prescribed medicines : hypodermic medication : use of apparatus on loan : proprietary and stock medicines, etc.

The relation which federated members should take up towards non-federated men was discussed, but no resolution was at present come to. It was decided to send a report of the proceedings to the Journals with the Ethical Rules ; but that the scale of fees and prices be only supplied to members.

Votes of thanks to the Chairman for presiding, and to Mr. Donald for the part he had in calling the meeting and the trouble he had taken in arranging the scales, concluded the meeting.

#### Rabies in Paris.

The Paris correspondent of *The Lancet* writes :—"The increase of rabies among dogs in Paris has now become alarming, and M. Martel, chief veterinary surgeon to the Prefecture of the Seine, has pointed out to the Academy the grave danger which threatens. In the Paris area 411 cases of rabies were reported in 1918, and 61 during the first 25 days of the month of January just past ; compare this with the 3 or 4 cases per annum with which we had to reckon in 1913 and 1914. 350 bitten people have attended the Pasteur Institute, and several deaths have occurred three of which are recent. Stray dogs without leash or muzzle are numerous in Paris. The disease is thought to have been carried by dogs abandoned by their masters in the war zone, and by others which have escaped from the camps established near Paris to test the effect of the new asphyxiating gases. M. Martel demands the application of strict police measures ; all dogs should be numbered, registered, and obliged to wear a collar with a medal attached certifying that the tax has been paid by their owners ; in addition they should all be muzzled. Stray dogs should be ruthlessly collected by police agents and brought to the special depot (*La Fourrière*) to be destroyed if not claimed within a week."

In the House of Commons, Wednesday, Feb. 19.

#### RABIES IN DEVON AND CORNWALL.

Colonel Sir ARTHUR GRIFFITH-BOSCAWEN, Parliamentary Secretary, Board of Agriculture, answering Mr. Carew, said :—"At present the outbreak of rabies in Devon and Cornwall cannot in any sense be said to be stamped out. The disease may show itself at any time within six months from its inception. The last case was confirmed on the 11th inst., and, in addition, there is still a number of suspected cases under investigation by the Board's veterinary department. The total number of cases confirmed by the veterinary officers of the Board to date is 118—Devon 94, Cornwall 24. The Board have reason to think that the responsible local

authorities are carrying out their duty as efficiently as their staff permits. I am informed that to date 18 civilians, two soldiers, and one sailor have been bitten and undergone the Pasteur treatment for hydrophobia.

### ARMY VETERINARY SERVICE

#### Extracts from *London Gazette*.

WAR OFFICE, WHITEHALL, Jan. 1.

His Majesty the King has been graciously pleased to approve of the undermentioned reward for distinguished service in connection with Military Operations in France and Flanders:—

\* \* \* \*

#### AWARDED THE MILITARY CROSS.

T. Capt. John Edgar Young, R.A.V.C., att'd. H.Q., 34th Bde., R.F.A.

Feb. 13.

#### REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Temp. Capt. A. Hart relinquishes his commn. on account of ill-health contracted on active service (Feb. 14), and retains the rank of Capt.

Feb. 15.

Temp. Capt. R. L. L. Hart to be acting Major while employed as D.A.D.V.S. (Jan. 5th).

Feb. 17.

Temp. Lt. P. McLaughlin to be temp. Capt. (Jan. 22).

Feb. 18.

Temp. Capt. (actg. Maj.) A. de R. Gordon, D.S.O. to be actg. Lt.-Col. while holding the appt. of A.D.V.S. (Feb. 25, 1918); Temp. Capt. A. de R. Gordon, D.S.O. from Gen. List to be temp. Capt. (April 19th, 1915); Temp. Capt. A. de R. Gordon D.S.O., to be actg. Maj. (July 1st, 1916). The follg. relinquish their commns. (Feb. 19th):—Temp. Capt. E. A. Phipps, on account of ill-health contracted on active service, and retains the rank of Capt.; Temp. Lt. G. J. Harvey, on account of ill-health, and retains the rank of Lt.

Feb. 19.

Capt. and Bt. Maj. G. E. Tillyard relinquishes actg. rank of Maj. on ceasing to hold appt. of D.A.D.V.S. (Feb. 10); Temp. Lieut. W. E. Barry to be temp. Capt. (Feb. 1st).

#### TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Feb. 17.

Capt. W. K. Townson relinquishes his commn. on acct. of ill-health contracted on active service (Oct. 11, 1918), and retains the rank of Capt. (substituted for that which appeared in *Gazette*, Oct. 10).

#### OBITUARY.

WALTER SEYMOUR ADAMS, Col., late A.V.C., Roslin Road, Bournemouth.

Graduated Lond: April, 1866.

Died 15th February, Aged 74.

THOMAS AUGUSTINE O'BRIEN, T. Lt., A.V.C., Jimerick. Died on Active Service, 6th October, 1918.

MARCH 1, 1919.

VOL. XXXI.

## OUR COUNCILMEN.

A contributor, commenting upon some recent effusions composed mainly of loose talk on the alleged but undefined misdeeds of our Council, offers a bet at tempting odds that none of these writers who are spilling ink under a *nom-de-plume*, and a large proportion of members who have not written but who are described as "seething with discontent" and "everywhere grumbling," could name the men who at present compose our legislative body. On consideration one does not quite see that they can be expected to do so. The only complete list published to the profession appears on the voting papers issued at the end of their year of office—just before the next election. It did appear in the Register, which is issued early in the year, not less than eight months after the elections; and a list of election results—the names of 8 of the 32 members—appears in the professional journals directly after the elections. The Annual Report contains no list, indeed, as issued at the same time as the voting paper it would appear superfluous. Thus, to preserve a record, it is necessary to retain the half of the voting paper, and correct it from the list published in the professional journals in June.

The hiatus would be avoided—when the new Bill becomes law and each member gets his copy of the Register—if the Register were published *after the elections*, say in July, after the July exams., instead of the December ones: and further, might show who were defaulters in respect of the Annual Fee.

As there is a more intelligent interest in the coming election than is usually expressed, and as not a little injustice has been exhibited against a body of men who have served the profession for the last four years probably better than any since the signatories to the original Charter of 1844, a list of the present Councilmen is appended.

## THE WORK OF THE R.A.V.C. AT THE FRONTS.

This week we conclude the lucid exposition of Major-Gen. Sir F. Smith, C.B., on the organisation of the Veterinary Service. Much of the information is already known to many of our readers: but the address is primarily intended for lay readers—an endeavour to inform the public, and to place the professional work in its proper perspective—and for that reason we have printed it in full. In the pages of the Journal of the Royal Society of Arts it will reach the eyes—possibly arrest the attention, of a group of intelligent readers. So far as the audience is concerned, it comprised members of the profession, members of the Society of Arts, and friends of the R.S.P.C.A., which has contributed largely in the matter of supplies to the success of the R.A.V.C.

It may be asked if it is not possible to widen the scope of the information by a further use of the now popular kinema. The views of the hospitals and rest camps would be entirely new to the general public; one, of a horse hospital under canvas is unique: so is one of horse lines under palms. Our old acquaintances, the mange parasites, is not so fresh, but another, of a group of African ticks, alive and in active movement, is particularly telling. The film of horses at exercise, on the plan suggested by Major, now Colonel, F. Eassie, in S. Africa in 1900, is also very telling. The horse ambulances, hospital operation, and equipment, are all informative, and with judicious additions and inclusion of a few figures would make a short and interesting "turn."

*It is useless to blame the general public for indifference to matters of which they are ignorant.*

This text has been urged in these columns for years past: and is slowly coming to notice. In respect to farmers, it is embodied in the address by Mr. G. P. Male, which appears on another page.

## TUBERCULOSIS IN A HORSE: ENORMOUS ENLARGEMENT OF LIVER.

By Captain J. F. D. TUTT, M.R.C.V.S., F.R.M.S.,  
Winchester.

*Subject:* Seven-year-old cart gelding.

*History:* The animal was bred upon the owner's farm; it had never received cow's milk when a foal.

Beyond an operation for hernia when a foal, the animal had never had a day's illness, nor appeared unfit, until early in 1915, when one evening the owner gave it a "Cupless" ball. From that day he refused to eat corn, but would eat hay in any quantity.

The patient was seen a few day's later, as the owner thought that "either the teeth required rasping, or that the throat had been punctured with a spar, with which the ball had been administered.

Examination revealed neither of these conditions, and at this time the animal was in good condition and was working daily. Faeces were quite normal.

The animal continued working until Jan. 21, 1915, when advice was again asked for, as he was now losing condition and still refused corn, but would eat hay with avidity.

Beyond a little yellowish discolouration of the mucous membranes, nothing was observable. There was a suggestion that he had had worms some time previously, and at the owner's express regret the usual vermifuge drench (*Ol. terebinth zii*, *Ol. lini Oj*), was given.

This acted freely, the horse scoured for a few days. A few oxyuridae were passed. From this time, the faeces never again returned to a consistency firmer than those from a cow.

He was then put on a course of Infusion of gentian and Sodii bicarbonate: and Extract of malt was given in each meal, *zii* doses.

No improvement followed, so it was decided to test for Tuberculosis.

This was done subcutaneously on Jan. 25th, and the following is the record of the temperatures:—

Initial temp.	9 hrs.	12 hrs.	15 hrs.	20 hrs.	24 hrs.
101.4	102.2	102.4	102.6	102.8	103.3

The temperature reaction, though not high, was regarded as very suggestive of the existence of tuberculosis.

The ophthalmic test was quite negative.

Ehrlich's test was applied to the urine, and a positive result was indicated by the port wine colour of the fluid and redness of the froth.

The animal continued to lose condition, and on Feb. 5th commenced purging, and from that date rapidly lost condition.

Feb. 9th. Appeared very itchy, and rubbed himself raw in several places. No parasites were detected.

Feb. 11th. Slaughter was advised, and was carried out the following day.

*Post-mortem examination.* Heart and lungs were sound. Liver enormously enlarged and cirrhotic: it weighed 102 lb. Mesenteric lymphatic glands were tuberculous. The spleen and kidneys were normal.

#### THE WORK OF THE BRITISH ARMY VETERINARY CORPS AT THE FRONTS.

By Maj.-Gen. Sir FREDK. SMITH, K.C.M.G., C.B., F.R.C.V.S.  
(Reprinted from the *Journal of the Royal Society of Arts*).  
(Concluded from p. 292).

The *Diseases and Injuries* of active service can only be very briefly dealt with. You will have gathered from the few remarks already made what a big subject it is, representing nearly the whole of animal inefficiency in war. A visit to a veterinary hospital in any theatre would reveal very few cases due to battle casualties, not for the reason that these do not occur, for the horse is a

far larger target than a man, but because such cases are usually dealt with on the field by destruction, only those being reserved for treatment which offer a prospect of complete recovery. Nothing short of complete recovery is of the least value where animals are concerned. In the matter of treatment, modern methods are adopted, and I may tell you that surgery has made many advances during the present war. Injuries and poisoning from gas attacks have been frequent, and it may be known to you that horses in the front line wear gas-masks. I will show you presently on the screen the destructive effect of gas on the surface of the body; the pictures are unique, and the artist a non-commissioned officer in the Royal Army Veterinary Corps.

Of mange I have already told you sufficient, and you will be able to visualise the insects at work when I come to the lantern demonstration. Of the pest *Lice* I have not previously spoken, though the subject is full of human interest: men are more easily affected than horses, and in days long gone by the infestation in peace time of people of position was not regarded as disgraceful, whilst among the poor not only was the presence of lice looked upon as an indication of good health, but the wanderings of these disgusting parasites on the head gave early warning of a change in the weather! In the days of Queen Anne we have it left on record that hunger and lousiness were two distempers which affected the soldier in war. The louse insect is not difficult to kill, but the egg is very resistant, and so causes repeated infection. *Ringworm*, another troublesome affection, is due to vegetable fungus, of which I will show you a picture. *Glanders* you have already heard a little about, and a picture of the organism which produces this loathsome affection will be shown to you. Perhaps I may here explain that the reason why this disease in any army has lost its terror is the advance of scientific knowledge.

A Russian veterinary surgeon discovered the fact that if the organism of glanders were grown in broth, and subsequently the whole mixture killed by prolonged heat and then filtered, the filtrate, known as mallein, if injected into a normal animal produced no effect, whereas if the horse were glandered a painful swelling arose at the seat of inoculation. This constitutes the mallein test to which I have so frequently referred. It was the greatest veterinary discovery of the nineteenth century, for it has enabled us to detect the presence of the disease at a stage when the animal cannot communicate it to others, and in this way to obliterate the pestilence. It is sad to relate that the discoverer subsequently died from glanders contracted during his investigations.

*Strangles* is a highly infectious disease common among young horses, and exists to an extraordinary extent among the animals collected on mobilisation. Its cause is a very small organism capable of being seen only under a high power of the microscope. It was the most serious pest we had to deal with at the beginning of the war. It frequently leaves behind it permanent inefficiency.

*Contagious Pneumonia* of the horse has led to an enormous monetary loss. During the early months of the war an average of thirty deaths a week for several months were occurring in one hospital in this country from this cause alone. The fat and young were the chief victims. Pneumonia is also the chief cause of loss among animals on board ship. Horses are not the only victims of contagious pneumonia; cattle are affected, and our transport oxen employed in the African campaigns have suffered seriously from this disease.

This reference to German South-West and German East Africa suggests the desirability of mentioning the other animal plagues existing in that continent, which have been responsible for enormous losses among military animals.

No more terrible pest exists than *Cattle Plague*, which is capable of killing off nearly the whole stock of a country. It has been a serious trouble in German East Africa, military operations having spread it far and wide. Fortunately it is possible, by inoculation, to protect animals against the disease.

The ravages of the *Tsetse Fly* you may have heard of. The part played by the fly is that it is the carrier of the disease, which is due to a large and peculiar organism in the blood, of which I will show you a picture. The fly is a blood-sucker, inhabiting well-defined zones of country, through which no animals can pass without becoming infected. The disease simply sweeps away the animal population, nor are its ravages confined to animals. A fly of the same species inoculates man with sleeping sickness. There are no less than ten clearly defined animal plagues due to different species of this organism. All of these plagues are not found in Africa: one affects India, another South America, and no cure is known for any of them.

*East Coast Fever* is an African disease of cattle, slow in action, but capable of inflicting dreadful losses. It also is due to an organism in the blood, but one of very small size. The disease is transmitted solely by the bite of an infected species of cattle tick, of which I will show you a picture, and you will also see on the screen how the ticks on animals are destroyed by arsenical baths.

The last African plague I will mention is commonly known as *Horse Sickness*. The organism which produces this is so minute that it has never been seen, and it readily passes through the pores of a porcelain filter. The disease is seasonal, and probably transmitted by a species of mosquito. It is a plague of terrible intensity; in a few hours hundreds of animals may succumb.

Less alarming than the African plagues I have mentioned, but still very serious, is *Anthrax*, a disease widely spread over the world, affecting almost all animals, including man, but especially horses and cattle. There have been heavy visitations of anthrax among our troops operating in Palestine.

There is a curious group of diseases which exhibits itself by *Ulcers* on the limbs and surfaces of the body. Two members of the group are highly contagious, one is due to a peculiar vegetable organism circulating in the lymph vessels, of which I will show you a picture.

Should a trace of the discharge from one of the many ulcers gain access to a wound in a healthy animal it sets up the disease. You can picture what it means if a case finds its way into the surgical section of a hospital. The affection lasts for months; it has given considerable trouble in Italy, but less in France, among our forces, though the French Army has suffered severely.

When large bodies of animals occupy the same camp for any length of time, especially in bad weather, the ground becomes foul to an extraordinary degree. This produces inflammation of the legs and parts above the hoof, the skin becomes gangrenous, and the hoof may even rot off. You will understand how difficult it is to combat such conditions, when military necessity demands that animals shall remain in a foul and contaminated locality; the disease can be controlled only by clean camping grounds and dry weather.

I must now make reference to the very large group of cases due to *Exhaustion*, the result of over-work. Fortunately there has been no insufficiency of food in the present campaign, owing to it being mainly a war of position; but when war is mobile it is impossible to carry bulky material like hay in anything like sufficient quantities, and grazing has to be resorted to if time permits. Even an abundance of food is no compensation for over-work and strain. The condition of the ground in France, and especially in Flanders, is common knowledge. Two and three teams of horses have had to be

employed to do the work of one, and when animal labour has absolutely failed, the guns and waggons have had to be man-handled. Age is another potent factor in the production of exhaustion; an old horse may easily be killed by one day of over-work. The exhausted war horse is a pitiable sight, and many never recover. A cold or wet night kills off scores. Nursing, rest, shelter, and proper diet are the only remedies, and I have given you a detailed account of how this treatment is carried out in convalescent depots.

*Saddle and Harness Galls* are the bane of active service. It would require a special series of papers to give you any real insight into the many causes operating in their production, and it needs several years' experience to learn practically how they may be prevented. Saddles and collars which fit horses in good condition do not fit them when the parts become smaller through loss of flesh nor will the most perfectly fitting saddle maintain a back free from injury when men have to remain mounted hour after hour. Under these conditions the skin actually dies through continuous pressure. I have briefly mentioned these two causes of sore back as giving you some notion of the magnitude of the difficulties of prevention, but there are many other causes in operation which are theoretically preventable, though in practice not always so. It is a common error to compare the shoe of a horse to the boot of a man—they both protect the feet, but there the analogy ends. The saddle of the horse may aptly be compared to the boot; both must fit, neither must be too large nor too small; a wrinkle in the sock or a knot in a lace may inflict considerable injury, for the reason that the boot must be free from all irregularities. You can imagine what it means to a back when the saddle blanket wrinkles, or a cake of mud exists between it and the skin, or a loose end of a strap finds its way under the saddle. Yet any of these things may readily occur when animals are saddled up in the dark. Such causes, however, cannot compare with the injury resulting from the arches of the saddle resting on the spine. The condition of back arising from this cause has to be seen to be realised.

I have yet to mention a serious disease among horses known as *Lock-jaw*. It is invariably the result of injury, and the chief seat of such injury is the foot. I cannot tell you how many thousands of animals in France have suffered from penetrating wounds of the feet due to nails picked up on the road. Fortunately, all such cases do not terminate in lock-jaw, but the inefficiency resulting from this class of injury has been so great that in France public notices have been erected urging that nails should not be thrown about. Many contrivances have been adapted to the feet, with more or less success, to prevent injury when a nail is trodden upon, and a form of electric road-sweeper has been devised which will pick up nails, on the principle of the magnet.

Lock-jaw frequently follows gun-shot wounds; especially has this been the case during the present campaign in France. The infection comes from the soil, particularly that which has been highly manured. An animal may be protected against this disease if a special antidote—prepared from the organism which produces the disease—be injected under the skin very early after the infliction of the injury, and tens of thousands of these doses have been given to horses during the present war.

A peculiar but well known eruption on the tongue, and mouth has proved at times a serious source of inefficiency during the campaign. The disease has a long name, which I will not inflict on you. A far more important matter is the extreme contagiousness of the disorder, and the great loss in "condition" which it occasions through the animal being unable to eat.

The last disease I shall refer to is a peculiar form of *Ophthalmia* affecting horses in France, which has resulted in very many cases of blindness. Towards the end of the campaign in South Africa the same disease was present, and occasioned a vast amount of inefficiency. It is no new disorder; its great terror in the field is its incurability and the extraordinary number of animals affected.

I have made no mention of the commoner troubles which fill a veterinary hospital, such as lameness, foot injuries and diseases, kicks, injuries of the organs of digestion and such like, but have focussed your attention on the larger and more serious groups, in order to give you a notion of the kinds of disorders with which veterinary hospitals have to deal in war.

Side by side with improved methods of treating disease, there have been going on during the whole campaign inquiries into the nature of diseases, and the study of their prevention, diagnosis and treatment. There are *Bacteriological Laboratories* in each theatre of operations, which have done valuable work. The subordinate staff of the laboratory in France are nearly all ladies. I trust that one outcome of the war will be the entry of ladies into the veterinary profession, for the smaller animals are especially suited to their care.

The whole of the Mallein employed throughout the Service is made in an army veterinary laboratory, hundreds of thousands of doses being sent out in the course of a year.

I must say a few words regarding the *Equipment* used in the field. Every veterinary officer is provided with a chest, containing, medically and surgically, all that he can possibly require, and up to date in every respect. Most of the drugs are in tablet form, so that no weighing is required; and the instruments, bandages and dressings are of the most approved type. This officers' chest is the outcome of many years experience and trial, and has proved a great success. When the officer is mounted he is provided with a leather wallet attached to the saddle, containing an emergency surgical outfit and drugs, all of the latter being hypodermic. Apart from the personal equipment of the veterinary officer, every unit has one or more chests containing dressings and emergency medicines, while the subordinate staff are furnished with a leather wallet containing simple remedies. Hospitals are provided with a complete medical and surgical outfit. I will show you these equipments on the screen.

Veterinary equipment is supplied in the field from an advanced depot of veterinary stores, where all replenishments can be effected; the advanced depots are supplied from base depots, while the base depots are supplied from this country. These operations are on an immense scale, and it is gratifying to add that the supply of stores for overseas has never once failed.

I wish time had permitted me to tell you something of the revolution the Veterinary Service has effected in the *Transport of Animals by Sea*. The horse is a bad sailor, but under skilled management the mortality has been reduced beyond belief. Large numbers of animals have been lost by enemy action at sea, and in this connection I cannot help referring to the captain of the s.s. "Canadian," who refused to leave his sinking vessel as he could not find his dog. He was last seen on the bridge standing at the salute!

I feel the responsibility I have incurred in attempting to present to you so large a subject within the limits of a single paper. I have had to discuss highly important questions in a few words, and through lack of time have omitted much I should have liked to say. I have only attempted to give a bird's eye view of the subject, and trust I have succeeded in showing that veterinary science

—“the Cinderella of the sciences,” as it has been aptly described — has done something during the present war to justify its existence.

In conclusion, I would draw attention to the fact that the comforts of war would not have been available for Army animals, had it not been for the generosity of the British public. I am sure that all of the 1,317,000 patients which passed through the various hospitals during the war, would tender their grateful thanks if they could. I am feebly endeavouring to do so for them.

[The lecture was given on Dec. 11th, His Grace the Duke of Portland K.G., G.C.V.O., in the chair. At its close, Maj. Genl. L. J. Blenkinsop, D.S.O. gave a brief *résumé* of the difficulties the Corps had encountered in the various fields; and on behalf of the A.V.C. thanked the R.S.P.C.A. for all they had done during the war. They had been the means of saving a vast amount of animals suffering. A vote of thanks to Sir F. Smith was proposed by the chairman; and a similar vote to the chairman followed.

We regret that restriction of space compelled us to print in four sections instead of two, as we had hoped. Also that it has not appeared earlier. Galley proofs were available on the evening of the lecture — with the usual proviso, that they were not to be used before publication in their Journal. By the time that appeared our limited space was filled with more urgent professional matter.]

#### ROYAL COUNTIES VETERINARY MEDICAL ASSOCIATION

[NATIONAL V.M.A.—SOUTHERN BRANCH.]

Address by Mr. G. P. MALE, F.R.C.V.S.

According to the rules of this Association the President is required to give what is called “A Presidential address,” but owing to great pressure of work I fear that the remarks I am about to make will fall short of the high standard set by former Presidents: at the same time I should like to take this opportunity of bringing to your notice and serious consideration matters which I have had in my mind for some considerable time which perhaps may be of some benefit to our profession, in whose welfare I take such a keen interest.

First, however, I should like to express my appreciation of the honour conferred upon me by your electing me to the chair of this association, in this year above all others. I feel that there were others who would have filled it better, but I yield to none in my wishfulness to advance its interests. We have had four long years of war, and we all feel tired. It has been strenuous work to carry on with depleted staffs, difficulties in transport, and hindrances from every quarter, and we should all like a rest and a holiday. There are yet fresh difficulties to face with the coming of peace: labour troubles are in the air, a reconstruction has to take place—the world is to be remade, and unless the veterinary profession is fully alive to its own interests, it will find itself left out in the cold, and instead of improved conditions there will be the reverse.

Now is the time for far seeing members of our profession to seize the opportunities offered. We have been content to jog along, each one busy with his daily routine of work, without thought to the benefit of the profession as a whole. Very little interest is taken with the doings of the Council, very few vote, and not many even read the reports of council meetings, so that we must not blame the Council if it is not all that can be desired—we must blame ourselves for our lethargy.

As an outsider open to correction, it does seem sometimes that a great deal of time is taken up by arguments

as to points of order and precedence and one sometimes wishes that some of the energy wasted on destructive criticism could be turned into something more helpful, more inspiring, and shall I say more ideal.

We as a profession seem to be shut off from all intercourse with the outside world. We harbour our old petty jealousies and forget that to improve our profession: we must go out into the world, especially the agricultural world, and show there that we are of use to agriculture, to science, and to mankind. Our finances are in a deplorable condition, and they get worse. Why? when this country is one of the finest agricultural countries in the world, and our stock is sought for by all the nations.

The fault is fully our own. How many agriculturists have even realised that their interests are very closely bound up with our own, and that if we as a profession advance in knowledge and position it is they that will benefit accordingly. I was talking to a noted stock breeder not long ago and he found it most difficult to believe that our finances were in such a deplorable condition, and he expressed the view that if it could only be brought to the knowledge of Breed Societies, Agricultural Organisations, and farmers generally that we could have not only their sympathy but their active support in reorganising them. Now is the time to do this. The government are desirous of assisting agriculture. Financially farmers are better off than ever before, and in helping us they will be helping themselves more than they know. Are we doing, as a profession, all we can to help stock owners by research work in animal diseases and in other improved methods of treatment?

With the exception of a few institutions, such as the Research Department at the Royal Veterinary College presided over by Sir J. M'Fadyean, who I might say here has done more than any other man in this country to investigate animal diseases; and the Veterinary Department of the Board of Agriculture with Sir S. Stockman at its head, there are few places equipped to properly carry out research; and even at these institutions there must be numerous difficulties both with regard to funds and facilities. Are all the schools alive to the necessity of improved educational facilities and veterinary research, and are they doing their best to forward it? I fear not. I am afraid their enthusiasm has waned under the difficulties presented. But why the difficulties? They chiefly resolve themselves into a want of funds, because the stock-owners have never been taught to realise the advantages of research, and so there has been no agitation for funds to be expended in this way, except by one or two enlightened Societies like the Royal Agricultural Society of England.

Also owing to the jealousy of the medical profession who, whenever there have been funds available for research, have used their great influence, I regret to say, for their own ends—to the detriment of the veterinary profession.

A good example of this occurred just before the war, when £200,000, called the Development Grant, had been allocated for research in connection with agriculture. An agitation was set on foot by a small number of pig breeders to alter the procedure in relation to swine fever. The medical pathologists took the opportunity to foster it, and at a meeting in Reading attended by nearly all the leading pathologists in England the veterinary profession was insulted by their proposing that an investigation should be carried out by their own profession, as we had failed. They afterwards, as a result, practically got the control of research work into their own hands, and, had not the war intervened, there is little doubt that our institutions would have received little or none of the money available. As I pointed out at the meeting, there were dozens of diseases which were

devastating the manhood of our country needing solution, *e.g.*, cancer, venereal diseases, cerebro-spinal meningitis, contagious diseases of children, such as measles, whooping cough, etc., and yet these pathologists wished to investigate swine fever, which, at that very time was being worked at with so much success by Sir S. Stockman at the Board of Agriculture laboratories. I regret very much to have to make these remarks, as I have so many good friends in the medical profession, but believe me they are, unfortunately, true, and unless more active steps are taken by our Council, and by the profession generally, we shall be left out again in any distribution of funds for research in animal diseases, and without funds it is impossible to carry out the lengthy and expensive investigation required.

The staffs must be paid adequately. Some of our leading veterinarians have told me that they cannot do this research because they haven't the staff. My answer is that, provide me with the money and I will obtain the staff very quickly. Why is it that a laboratory worker should be paid worse than a navvy? This must be altered; otherwise you will never get men to undertake it.

Our professors and lecturers, with few exceptions, are overworked and underpaid, so have little time and no funds to devote to experimental work; also no assistants to help them in the routine of the laboratory. Our colleges are lacking in the requisite laboratories and experimental field stations, whereas in other countries the State helps them in funds and encourages them in every possible way.

There are signs now that State aid is to be given for scientific purposes, but I have not yet heard of any move being made by those who should look after our interests to influence the State or public opinion as to our needs.

A Ministry of Public Health will shortly be formed in this country, but as far as I know no veterinary surgeon or veterinary pathologist has been asked to assist or advise, yet the relation between human and animal diseases is most intimate, and the collaboration of medical and veterinary pathologists could not fail to be of the greatest benefit to the country and the public health.

Human pathology owes much to the veterinarian. Griffith Evans, a veterinary surgeon, made in 1880 the momentous discovery of the trypanosome as a cause of disease in animals and man, and was the means of saving tens of thousands of human lives. He is but one example: numerous others could be quoted.

Again, there is a great demand by the public for a clean milk supply, and very shortly a new Milk Bill will be brought before Parliament which may seriously affect the veterinary profession. The last Milk Bill was never passed, owing partly to the outbreak of war, but the position of the veterinarian in that Bill was not a very enviable one. Are our interests being looked after and safeguarded in the draft of the new Bill? or are the medical profession to get the control of our services and our experience. We, as a profession, would probably not have been utilised at all, except for the inevitable protests of owners of live stock to the interference of men who have no practical knowledge of animal diseases. While the Council discuss matters of precedence and rules of debate, vastly more important matters are being settled without our being adequately represented as a profession.

If the Council have done all they can in these matters, and it is necessary for the rank and file of the profession to help, let them indicate in what way we can be of assistance, and if it is necessary let us return a member of our own to Parliament to look after our interests. This would require funds, but when the new Bill is passed it is to be hoped the necessary funds will be obtained, so that the Royal College will be able to pay its way and devote the surplus to some such object.

Speaking of the new bill, are all the steps necessary to get this bill through the House of Commons being taken? I am quite sure that there would be no difficulty in passing any well thought out scheme for the benefit of the profession if individual members approached their Members of Parliament; but we are in the dark as to what is required of us.

The veterinary profession have deserved well of this country.

Those who have had the privilege of entering the Royal Army Veterinary Corps have done splendid work, and I should like to quote the words of General Birkbeck, the Director of Remounts.

He says "our army had produced an unexampled veterinary service and their preventive hygiene had been beyond all criticism."

Sir J. Cowans Quartermaster General in his announcement that the King had been graciously pleased to raise the A.V.C. to the status of a Royal Corps said "The corps by its initiative and scientific methods has placed military veterinary organisation on a higher plane. The high standard which it has maintained at home and throughout all the theatres has resulted in a reduction of animal wastage, an increased mobility of mounted units and a mitigation of animal suffering unapproached in any previous military operations."

Those who have stayed at home, owing to ill-health, age, or some other good reason, have carried on with great fortitude without honour or glory, and have done their best under great difficulties to preserve the live stock of the country, to prevent contagious diseases which at one time looked like devastating the country, and to assist the decrepit and underfed horses remaining on this side of the water to do their work.

Others have done yeoman service as civilian veterinary officers in various army units and hospitals; especially was this the case at the beginning of the war, when the personnel of the A.V.C. was so small, and when officers with no experience of horses were in charge of animals newly arrived from Remounts, probably suffering from mange, ringworm, strangles, influenza, or pneumonia, with no farriers, dressers, or organised staff, and probably no shelter from wind and weather. The civilian veterinary surgeon then saved the situation.

In other spheres the veterinarian is looked upon as the friend and adviser of the farmer and stock owner. His opinion is constantly sought as to the soundness of horses, and when a contagious disease affects the animal population he is called in to eradicate it, or to lessen its depredations.

Individually he is looked up to as a scientific man, practical withal, but collectively veterinarians are neither properly recognised by scientific bodies nor by the State, and even agricultural organisations have not realised how much they owe them.

The Board of Agriculture is pre-eminently the body that should look after our welfare. Is it doing it? I fear not. It is only recently that a laboratory worthy of the name was established for the investigation of animal diseases.

The Local Government Board looks after the interests of the medical profession, who are well represented there, in fact a medical man Dr. Addison is now at the head of the department. The Board of Agriculture must look after the Veterinary profession in the same way, not for our sakes but in the interests of Agriculture which it should represent.

Agriculturists owe a great deal to the veterinary Staff of the Board, though I fear the department in its modesty has not advertised the fact. Only recently a vaccine has been prepared for the prevention of abortion in cattle which is proving most successful.

A serum is now in use for the protection of pigs against swine fever. Other diseases e.g. joint ill in foals,

are being investigated; pamphlets are written on the management and diseases of live stock, and in all sorts of ways the veterinary staff are assisting agriculture.

I should like to see a greater sympathy between the veterinary department and the owner of live stock, and also between the Board of Agriculture and the veterinary profession.

If individual agriculturists consult the veterinary surgeon on all matters concerning the health and management of their stock, surely the Board of Agriculture should look after their interests, provide funds for research, and not allow our colleges to be bankrupt, depending for money on the fees of their students.

I trust that in the coming year sufficient funds and facilities for research may be provided, so that many diseases of live stock may be investigated, and especially those which are communicable to man, and perhaps those diseases which are common to both, such as cancer tuberculosis, influenza and pneumonia, may be dealt with. Up to the present the medical profession have made comparatively little headway. Cancer research is almost stationary although huge sums have been spent, the deaths from influenza and pneumonia have been estimated to total 6,000,000 persons in 12 weeks, being five times more deadly than war. With regard to tuberculosis 150,000 persons are disabled every year—and yet the leading medical pathologists beg to be allowed to investigate swine fever! Influenza and pneumonia epidemics were common among horses at the beginning of the war, but I am glad to say owing to the preventive measures taken, and with proper treatment, the losses were reduced to a minimum.

The experience and assistance of veterinary surgeons in investigations into these and other diseases should be of the greatest benefit to the medical pathologist, and to the State, but it is noteworthy that the veterinarian is not called in to assist.

We are a small profession and an isolated one, but the time must come when we shall have proper recognition. We must educate public opinion—that is the only possible way to get things done; and if I have done nothing more this afternoon than indicate some of the ways in which this can be accomplished I shall be satisfied.

I trust the Council will do their utmost to advance our interests. I care not whether the Council is composed of all the teachers from all the Colleges, or wholly of practitioners. It matters not what clique or party pulls the strings so long as they look ahead to safeguard the interests of this noble profession, which I have so much at heart. If I have said anything to wound their susceptibilities I make that my excuse, and plead forgiveness, but I am firmly convinced that energetic measures are required at once to convince public opinion that State aid must be given to our colleges, and that veterinary research must be encouraged, and supported by requisite funds.

Veterinary Surgeons must take more interest in public bodies, and especially scientific institutions.

Agriculturists must realise the close intimacy between our interests and their own.

Members of Parliament should be approached, their aid sought, and if necessary one of our own members should be returned to the House of Commons.

If these things are done now, I am sure that the men coming back to their practices after the horrors of war will find that we have not been idle while they have been away and that the status of the profession has been raised, and instead of being a bankrupt profession we shall have sufficient funds to pay our lecturers and our scientists adequately, to equip our colleges, to provide research stations worthy of our calling, and that we shall be enabled to devote our energies to the elucidation and treatment of disease for the benefit of agriculture and the good of the whole State.

### "ACTINOMYCOSIS IN A MARE TREATED WITH AUTO-VACCINO-THERAPY."

Sir,—Replying to Major Ascott's letter in your issue of the 15th, inst I have much pleasure in stating the mare had her first injection on April 20th 1918, and the dates of the subsequent injections are as follows—April 27th, May 5th, 14th, 21st, 29th June 7th, 15th, 23rd, 30th, July 8th, and 17th. It will be seen the period covered by the vaccine treatment was 89 days, and as already stated in my article the number of injections given were twelve in all. I had hoped others would discuss the points raised, for I am sure there must be several debatable ones—perhaps there are many. Healthy constructive criticism does everyone good, and that is one important reason why one should record his observations in the professional journals but I do not mean the criticism of those curmudgeous met with, unfortunately, in every walk of life, whose main object appears to be to black ball every opinion or observation honestly put forward, save those found in the idols of their own production.—Yours etc.

Friarn House  
Bridgwater.

W. SCOTT.

### THE IMPORTED DISEASES.

Sir,—In a leading article in your issue of February 22nd.

I was one of those who a week or so ago received two of the circulars from the Board of Agriculture to which you refer and I think that all practitioners agree that the step taken by the Board is a wise one and should have their entire support if only it could be carried out without too much red tape.

I know a veterinary surgeon who some while ago had an unusual case in a dog. The animal died and the veterinary surgeon made a post-mortem examination expecting to find something to account for its death and previous behaviour. All organs were found to be healthy and the cause of death not ascertained; at the same time something was found which, with the dog's history, raised a certain suspicion, with the result that the animal's head was sent to the Board and a letter sent giving full particulars of the case and asking that the brain might be examined. The veterinary surgeon informed his client that the post-mortem was unsatisfactory, and suggested the further examination which was agreed to. The following day a wire was received from the Board telling the veterinary surgeon to report the case to the police. Result—a constable visits the owner, orders a pet house dog which had never been in contact to be shut up in a small outhouse until the Board was heard from (movement of this dog to a proper kennel for quarantine being refused, to the owner's indignation) which was not for three weeks, the animal being meanwhile under the inspection of the police and of the local veterinary inspector. The veterinary surgeon concerned received no further communication whatever from the Board beyond the telegram mentioned.

This is rather long winded, but my point is this—Is not such action conducive to what you aptly term in your article "clinical error" and opposed to the object of the circulars. For what practitioner could stand many such rackets in his practice? Surely the veterinary surgeon—if all this was necessary—might at least have held the live dog in quarantine during the Board's pleasure, and so saved his client all the inconvenience and annoyance—Yours truly,

24/2/19.

"ONCE BITTEN."

### THE PHARISEES.

Sir,—May a middle-aged practitioner in a big city miles away from Cumberland, who has never seen that county or known a single veterinary surgeon in it, offer some comment upon the lengthy report under the heading "Cumberland practitioners and their fees" in the *Current Record*? So far as I can judge from the report, the proceedings seem open to criticism; and certainly, the method of reporting them leaves much to be desired.

I only discuss the actual business transacted. First an "ethical code" was adopted, concerning which I indicate one point. A good proportion of it consists of rules which most of us agree should always be observed between all members; and I may add that infringement of one of those rules (that against soliciting) has been followed by removal from the register. Yet we are told that these rules are "only to operate as between subscribers to this scheme," who are allowed "freedom of action and practice" in dealing with competitors outside. This alone is somewhat ominous; and there is more to follow.

The next decision reported concerns the "F.P.D. Panel System," I, and I fancy many other practitioners, know nothing about this; and some explanation and discussion of its provisions might have been useful to many. Nothing of the sort is given. All we are told is that the Cumberland union will have nothing to do with a scheme which seems to have been generally acceptable to other veterinary surgeons, on the ground that its terms and conditions are "little less than an insult to the profession." No indication of what the objectionable features are is given; but it is added that nobody holding one of these appointments shall be admitted into the Cumberland combine—another significant pointer.

Next comes the most important business—the fees and charges. Why are we told so little about these? A mileage scale, apparently an absolute minimum, has been fixed. A scale of fees has been fixed and charges "recommended"; but all these scales are only to be supplied to members. They would certainly have been useful to practitioners outside; and some other questions suggest themselves. Are these scales obligatory upon the members, or merely "recommended" to them? Will an outsider desiring to join the combine be expected to accept the scales blindfold? If the fees demanded for official work (Board of Agriculture, etc.) exceed those usually given, how is it proposed to obtain them? If so much essential information was to be withheld, what was the use of publishing the proceedings at all.

As a final fillip to our curiosity, we read that "The relation which federated members should take up towards non-federated men was discussed, but no resolution was at present come to." Does not this suggest that these non-federated men are in danger of professional ostracism? I may be wrong; but that is the impression which the whole report has left on my mind, and it is not a pleasant one. So far, the federation only numbers about two-thirds of the men now practising in Cumberland; and, if these decide to treat the remaining third as pariahs unless they join the combine, what kind of professional brotherhood is likely to prevail in the county?

Perhaps some other onlookers will give their opinions, or someone with knowledge may enlighten me. Let me add that I firmly believe in the value of combination; but there are right ways and wrong ways of setting about it, and at present it looks to me very much as if these Cumberland practitioners had chosen the latter.

Yours truly, "TOWNSMAN."

## ARMY VETERINARY SERVICE

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Feb. 21.

The Secretary of State for War has received the following dispatch:—

General Headquarters,  
Mesopotamian Expeditionary Force,  
November 11, 1918.

Sir,—With reference to paragraph 29 of my dispatch dated October 1, 1918, I have the honour to submit herewith a list of names of those officers serving or who have served under my command, whose distinguished and gallant services and devotion to duty I consider deserving of special mention.—I have the honour to be, Sir,

Your obedient servant,

W. R. MARSHALL, Lt.-Genl.,  
Commander-in-Chief,  
Mesopotamian Expeditionary Force.

\* \* \* \*

T. Capt. J. J. M. Barry, T. Capt. W. T. Ferguson,  
T. Capt. J. R. Hewer, T. Capt. J. Robertson, Capt.  
(T. Major) T. L. Shea, Capt. (A. Major) G. Williamson.

## REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Feb. 21.

Major J. R. Steevenson, D.S.O., to be actg. Lt.-Col. whilst holding the appt. of A.D.V.S. (Dec. 21, 1918).  
Capt. F. W. Pawlett, T.F., relinquishes the temp. rank of Maj. on ceasing to hold the appt. of D.A.D.V.S. (Jan. 31).

Capt. J. G. MacGregor, T.F., relinquishes the actg. rank of Maj. on ceasing to hold the appt. of D.A.D.V.S. (Dec. 17, 1918).

Temp. Capts. to be actg. Majs. whilst holding the appt. D.A.D.V.S.:—W. P. B. Beal (Dec. 5, 1918); J. N. Glass (Dec. 18, 1918).

Temp. Lts. to be Temp. Capts.:—H. Cooper (Jan. 8); A. D. Sanderson (Jan. 11).

Feb. 22.

Temp. Capt. D. G. Davies relinquishes his commn. on account of ill-health (Feb. 23), and retains the rank of Capt.

Temp. Qrmr. and Capt. A. T. Youles relinquishes his commn. on account of ill-health contracted on active service, and retains his rank (Feb. 20).

Feb. 24.

Capt. and Bt. Maj. G. Williamson relinquishes actg. rank of Maj. on ceasing to comd. a Vety. Hospital (Nov. 20, 1918).

To be actg. Majs.:—Temp. Capt. E. B. Reynolds (Dec. 6, 1918). While holding the appt. of D.A.D.V.S.:—Capt. C. R. Chadwick, T.F. (Dec. 2, 1918); Capt. U. W. F. Walker, M.C. (Dec. 7, 1918); Capt. H. E. A. L. Irwin (Dec. 20, 1918).

Feb. 25.

The War Office announces the following casualty:—  
Died: Major W. H. Taylor.

## OBITUARY.

W. H. TAYLOR, Major, R.A.V.C.

Graduated Lond: July, 1905.

ALBERT WILLIE OXENHAM, Mountain Ash, Glam.

Edin.: Dec. 1894.

Mr. Oxenham's death occurred on Feb. 10, at the age of 46.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1600.

MARCH 8, 1919.

VOL. XXXI.

## THE ANIMALS (NOTIFICATION OF DISEASE) ORDER OF 1919.

This Order, which came into force on the last day of February, differs little at first sight, but nevertheless materially, from the Order of 1910 which it supersedes. The important alterations are that dogs and cats are now included among the animals in which veterinary surgeons are required to notify scheduled disease, and that rabies becomes one of the diseases the existence or suspected existence of which is to be reported to the M.O.H. by the local inspector. There are one or two minor changes. In the section requiring the local inspector to transmit reports to the Local Authority and M.O.H., the words "Sanitary district in which the animal or carcass is" are followed by "or was at the time of its death." This casts an additional obligation on local inspectors in some cases. Sarcoptic and psoroptic mange are now formally included in the Order, although excepted from the diseases which the practitioner is required to notify to the police.

Practically the Order is an amendment of the imperfections of the old one, especially with regard to rabies. The 1910 Order took no cognisance of rabies in dogs and cats; the present one removes that flaw, and leaves no loophole for any practitioner who may be inclined to evade his duty.

### "OUR OWN MEMBER."

More than once in the last generation the idea of having a Veterinary M.P. to represent our interests in the House has been discussed; and recently it has again been mentioned. The last time it was before us was some thirteen years ago, when, after causing much discussion, it was quietly dropped. Several reasons accounted for this. The difficulties in the way of carrying out the plan became clear upon close examination; while no concrete proposals for surmounting them were put forward. It was recognised, too, that considerable influence could be exerted upon the government in other ways; and there was a certain doubt whether a single Veterinary M.P. would be more effective.

Except that the payment of M.P. has lessened the possible financial difficulties, the position to-day is much the same as in 1906. How to get a veterinary surgeon into Parliament at all remains a problem; though circumstances might arise to simplify it. It is still doubtful whether a veterinarian in Parliament could exercise more influence upon the Government than can be done by the Parliament of our own profession; and it is certain we have other good methods of pressing our claims in

the House. Much can be done by individual veterinarians getting in touch with and informing their local M.P.; and probably this line has never yet been sufficiently worked by the profession generally. Any member of the House with a genuine interest in our affairs might do nearly as much good as one of our own profession; though professional knowledge should render a veterinarian preferable, if he were suitable in other respects.

A further consideration is that a veterinary M.P.—one voice in more than 700, speaking for one of the smallest professions in the kingdom—would have an uphill task; and the chances of success would depend very largely upon the quality of the man. Our present President, for instance, who unites intimate knowledge of our needs, and long experience in close touch with Government Departments, with a level head, and a gift of lucid expression, might attain our ends, and would certainly do us good in some directions. One asking impossibilities, one lacking in tact, or one unduly given to verbosity, are only a few specimens of several possible representatives who could only do us harm. Since 1906 we have made good progress without a member, and might continue to do so. It would be better to remain unrepresented than have a representative of the wrong sort.

## A PECULIAR CASE OF SHOULDER LAMENESS.

By Captain G. E. OXSPRING, R.A.V.C., Khartoum.

The subject of this report was a Cyprian mule gelding, 15 hands, aged 12 years, belonging to an Artillery Unit. He had three years service, during which time no lameness was recorded against him.

The animal was admitted to Hospital for lameness in the near fore limb. The shoulder muscles were at this time slightly atrophied, when walked or trotted the shoulder joint was not properly extended, and the limb was carried in the way which is typical of shoulder lameness. Manual examination revealed nothing as to the actual cause.

Treatment at first, was hot fomentation and massage to the muscles, and rest. After two weeks, there was no improvement, so it was decided to blister an area including the shoulder joint and part of the scapula muscles. Two months rest was allowed, and as the case was worse than ever, and the muscles were greatly atrophied, it was considered to be incurable, and therefore destroyed.

At the Post Mortem examination, a bony growth was found on the cartilage of prolongation, near the cervical angle of the scapula. The enlargement

was nearly circular in outline with a diameter of 3 inches, and it extended through the depth of the cartilage, the remainder of the latter was quite normal.

From the dorsal surface of the growth, a large part of the supraspinatus muscle took origin, the fibres of which appeared to pass into its substance.

As there was no sign of external injury in this region, nor any knowledge of one having occurred, it seems probable that the condition started as the result of a sprain or rupture of the supraspinatus muscle at its origin.

### EPITHELIOMA OF THE PENIS IN A PONY.

By Captain J. F. D. TUTT, M.R.C.V.S., F.R.M.S.,  
Winchester.

The subject was an aged pony, used for occasional short journeys into town.

*History:* The owner came to me on September 3rd, 1915, and requested me to see the animal, as it had great difficulty in urinating, and the sheath was very much swollen. It was also rapidly losing condition. As it was an old favourite he desired to have it remedied if possible.

On arrival at the stable, I examined the sheath, and endeavoured to withdraw the penis, but was unable to do so on account of the swelling. I was able to feel that the tip of the penis was rough, and that a growth was present, and I accordingly advised surgical measures.

An operation was carried out on Sept. 7th. The animal was cast and anaesthetised, and when well under the influence of the anaesthetic, the penis was withdrawn, but only with the greatest difficulty, and when secured with a piece of tape, was found to be covered with cauliflower-like excrescences on the end, and for a length of five inches was greatly enlarged and hardened.

The urethral opening was practically obliterated, and it was impossible to insert a catheter, even when the canal was slit open for a length of 3—4 inches. The healthy portion of the penis was secured by a piece of tape, the ends of which were held by an assistant.

The diseased portion was then carefully removed, and the slit portions of the urethra were sutured to the end of the stump in such a manner as to diminish the risk of stricture.

The patient made a good recovery and was able to urinate quite freely until its recent destruction on account of age, etc.

Prior to the operation just described, a previous operator had removed some papillomata (according to the owner) some two years before.

*Microscopical Examination of Growth.* A paraffin section was obtained in the usual way, cut and suitably stained.

The penis was found to be infiltrated by an extensive malignant growth, having the structure of a squamous epithelioma. It was composed of ingrowing epithelial columns with cell nests and keratinoid changes—exactly like the same growth in man.

### ORDER OF THE BOARD OF AGRICULTURE AND FISHERIES. (DATED 24TH FEBRUARY 1919.)

#### ANIMALS (NOTIFICATION OF DISEASE) ORDER OF 1919.

The Board of Agriculture and Fisheries, by virtue and in exercise of the powers vested in them under the Diseases of Animals Acts, 1894 to 1914, and of every other power enabling them in this behalf, do order, and it is hereby ordered, as follows:—

##### *Application of Order.*

1. The diseases to which this Order applies are cattle plague, contagious pleuro-pneumonia of cattle, foot-and-mouth disease, sheep-pox, sheep-scab, swine-fever, anthrax, epizootic lymphangitis, rabies, glanders and farcy, and sarcoptic and psoroptic mange of horses, asses, or mules, and the definitions of "disease" and "diseased" in the Diseases of Animals Act, 1894, are extended for the purpose of this Order accordingly.

##### *Notification of Disease.*

2.—(1.) A veterinary surgeon or veterinary practitioner who in his private practice is employed to examine any head of cattle, or any sheep, goat, swine, horse, ass, mule, dog, or cat, or the carcase of any such animal, and is of opinion that the animal is diseased, or was diseased when it died or was slaughtered, or suspects the existence of disease therein, shall with all practicable speed give notice of the existence or suspected existence of disease to an Inspector of the Local Authority, and also, except where the disease is anthrax, sheep-scab, glanders or farcy or sarcoptic or psoroptic mange of horses, asses, or mules, to a constable of the police force for the police area in which the animal or carcase is, or was at the time of its death, who shall transmit the information to the Board of Agriculture and Fisheries by telegram addressed "Agrifi London."

(2.) An Inspector of the Local Authority on receipt of notice under this Order shall forthwith report the existence or suspected existence of disease to the Local Authority, and if the disease is anthrax, glanders or farcy, or rabies, also to the Medical Officer of Health of the Sanitary District in which the animal or carcase is, or was at the time of its death.

(3.) The notification of disease hereby prescribed shall be in addition to any notification prescribed by any other Order relating to the disease.

##### *Communication of Information of Disease by one Local Authority to another.*

3. Where a Local Authority receives under this Order or otherwise information of the existence or suspected existence of disease in relation to a carcase of any of the above-mentioned animals that has died or been slaughtered in the District of another Local Authority, the Local Authority shall forthwith transmit the information to the other Local Authority.

##### *Fee for Notification.*

4.—(1.) A veterinary surgeon or veterinary practitioner who under and in accordance with this Order gives notice of the existence or suspected existence of disease to an Inspector of the Local Authority shall be entitled to receive from the Local Authority a fee of two shillings and sixpence for each notification.

(2.) Where two or more animals or carcasses are examined by a veterinary surgeon or veterinary practitioner on the same premises and at the same time and are found to be diseased, or are suspected of being diseased, one fee only shall be payable to him in respect of the notification.

#### ROYAL COUNTIES

#### VETERINARY MEDICAL ASSOCIATION.

(NATIONAL V.M.A.—SOUTHERN BRANCH).

The Annual General Meeting and Dinner was held at the Great Western Hotel, Reading, on Friday, February 14th, when the President, Mr. G. P. Male, presided, and there were also present the following:—Vice-Presidents: Messrs. J. Willett, Hon. Treasurer, London; J. H. Parker, Faringdon; and R. J. Verney, Hon. Auditor, Oxford; also J. C. Coleman, Hon. Secretary, Swindon; J. B. Buxton, London; E. Brown, London; J. R. Baxter, Lechlade; T. W. Lepper, Aylesbury; H. A. MacCormack, London; W. Pauer, Blackwater; S. H. Slocock, Hounslow; and Mr. F. W. Willett, Staines. Major F. J. Taylor was present as a visitor.

The Hon. SECRETARY announced apologies from Sir J. M'Fadyen, Sir Stewart Stockman, Messrs. Trewin, G. E. King, T. B. Goodall, J. Varney, F. W. Cundell, J. East, J. McIntosh, J. McKelvie, S. Pennington, W. T. D. Broad, F. Bazley, W. C. Hazelton, Major P. J. Simpson, and Professor Wooldridge.

A letter was read from Mr. Adams asking that the R.C.V.M.A. would send a representative to meet the Insurance Companies, re examination fees for horses and cattle.

The SECRETARY explained that the Insurance Companies were having a meeting to discuss the fees paid to veterinary surgeons for examinations.

The PRESIDENT thought Mr. Adams had written to the Insurance Companies and they had said they were willing to meet him. He then wrote to Prof. Wooldridge, Secretary of the National, asking him if he would go on behalf of that society. The meeting was then postponed and Mr. Adams asked the Royal Counties to send a representative at very short notice. Mr. Willett was going to represent at that meeting which was postponed. They could now either elect a representative, or ask Mr. Willett if he would be good enough to represent them at the meeting to be held in London.

Mr. WILLETT said that a little while ago he said that he would not examine animals under a certain fee. He was told there was a meeting of Insurance Companies with a view to coming to some arrangement with regard to the fees paid. As he only acted as a referee at special fees, he would prefer that some other member should be their delegate, one who was more conversant with the procedure.

The PRESIDENT pointed out that some years ago the National went into the matter. A sub-Committee was formed and they met the representatives of the Insurance Companies. But neither party agreed, and the matter was left in abeyance. That was before the war.

The PRESIDENT then proposed that Mr. F. W. Willett be their representative. He was handy to London. The Secretary seconded and the proposal was agreed to.

Mr. PAUER asked if it would not be well to know Mr. Willett's views. Possibly he was in favour of half-a-crown fee.

Mr. WILLETT replied emphatically that he was not. It ought not to be done under half-a-guinea. There ought to be a sliding scale according to the number of animals.

The SECRETARY: That is so under scale A. I believe that at present there are two scales adopted generally all over the country, one where you get a fixed sum of 5/-, and the other where you get 3/- if more than one, and mileage for over three miles. Then there is scale A in which you are paid a much higher fee and no mileage. I always go under scale A which is a sliding scale according to the value of the animal.

Mr. PAUER: You are referring to only one particular Insurance Company?

Mr. COLEMAN : No. This is the scale of the whole amalgamated Insurance Companies. They have a sort of union who fix their fees.

Mr. PAUER : I have never yet seen these fees.

Mr. COLEMAN : They have them, but if you don't ask for scale A fees you won't get them. If you demand them they will pay you. The scale is agreed to by all the Insurance Companies.

A letter was read from Sir Stewart Stockman in which he said that if the Royal Counties liked to have a meeting in the Board of Agriculture laboratory, Addlestone, during the year he would be pleased to receive them; and he would give a demonstration on any particular matter of interest provided it was something in connection with which there was abundant material.

The PRESIDENT said he was sure they were grateful to Sir Stewart for inviting them. On several occasions they had most instructive meetings there. If it was their wish a letter would be written to Sir Stewart thanking him very much for the kind invitation and asking whether the April meeting would suit him.

Mr. J. WILLETT proposed that the next meeting be held at the B.O.A., laboratory, failing that at Reading.

The meeting unanimously approved of the suggestion.

#### REPORT OF SUB-COMMITTEE *re* VETERINARY FEES.

The PRESIDENT said they would remember that at their last meeting a sub-Committee was formed to draw up a scale of suggested minimum fees for that Association. There were on that sub-Committee Messrs. Coleman, Parker, F. W. Willett, Hancock, and himself. Some other members were not able to come, but Mr. Coleman, Mr. Willett, and himself went into the matter very fully, spending three or four hours over it. Mr. Coleman would read the recommendations they made.

#### *Minimum Fees Recommended.*

Town visits 3/6. Mileage 1/3 per mile. It is also recommended that an additional fee be charged for each additional animal examined.

Foaling or Calving 1 to 2 gns; Removing placenta 10/6 mare, 7/6 cow; Inflation of udder, Milk-fever 5/- *Medicines*. Draughts, cows and horses 2/6; Drenches, cows, cleansings etc. 2/-; Lotions 8oz 2/6; Liniment 8oz 2/6; Blister 2/6 to 5/- according to size; Powders, horses and cows, 8/- per doz; Balls 1/6 each; Pessaries 1/- to 2/- each.

*Dog Medicines*. Pills 1/6 per doz; Medicine 2oz 1/6 6oz 2/6; Powders 2/6 per doz; Worm capsules 1/- each; Whelping 10/6 to 21/-; Castration with Chloroform 21/-; Board and Treatment at Infirmary 2/- per diem.

#### *Operations. Horses etc.—*

Castration horses, Single 21/-, Two 15/-, Three or more 10/6 each; Docking 5/-.

Castration calves 2/6 each; bulls 1 year and over 10/6 each.

Ringling Bull 5/- (ring extra.)

Intratracheal injection 5 3/8 each, up to 10 2/6 each, above 10 2/- each.

Anti-abortion, 1 to 5, 5/- each; up to 10 2/6; above 10 2/- each.

Tuberculin test Single 21/-; Next two 10/6 each; After first three, 5/- each.

Anti-Tetanin Injection 7/6 each.

Raising and slinging horse 10/6; Hire of slings 2/6 per week.

It is to be especially noted that the above are minimum fees.

The PRESIDENT thought the fees were fair charges, and in reply to a question said that the 25% would be in addition. The War Office and the County Council paid 7½d. per mile each way.

Mr. J. WILLETT : Have you any information from the National with reference to these fees?

The PRESIDENT : No.

Mr. WILLETT said he was present at the last National meeting when he called attention to the fact that they were discussing the question of fees at the Royal Counties, that they considered the matter urgent, and that the National should again take the matter up, and get from the different societies their recommendation.

Mr. F. W. WILLETT asked if any scale of fees could be considered in regard to examining cows for councils, and so on, any figure for the examination of udder and signs of tuberculosis. Under special circumstances they got a stated sum for that, but it did not come under the Tuberculosis Order. He was an inspector for three councils, and before the war, if they found a tuberculous udder it had to be reported to the inspector of the local authority.

The PRESIDENT : I think the Tuberculosis Order will very soon come into force again.

Mr. F. W. WILLETT continuing, said that the Inspector of the Board of Agriculture, or the County Council Inspector then took the matter out of their hands. He would like to know what should be the charge, and considered it ought to be a shilling per cow.

Mr. COLEMAN (hon. sec.) said the County Council allowed a shilling per cow. When he had a case reported to him he used his discretion as to examining the other cows. They allowed a shilling for each cow examined beyond the one or two reported.

Mr. F. W. WILLETT : We are supposed to examine them once or more quarterly.

Mr. PAUER : I have been having about 1/6 a cow for quarterly inspection.

The PRESIDENT drew attention to the fact that a lot of these inspections were by unqualified men, inspectors of nuisances, etc. He considered that a matter which should be gone into.

A MEMBER : Doctors examine in some cases. A farmer told me that a doctor came down to inspect his cattle in the summer time. He was just going to market, so he said : "you go out and look at the cows, I shall be down directly." The doctor went out into the field and came back very pleased. He said "you have a ripping lot of cows. They look in a very healthy condition, I never saw them look better." He had inspected the store stock and didn't see the milk cows at all! (Laughter)

Major TAYLOR : Do you propose to make extra charge for night visits?

The PRESIDENT : We discussed that last time and sent a notice to each member saying that double fees would be charged for night work. It has already been agreed upon.

Mr. J. WILLETT : That should be embodied in any report we make. There is the question of time, summer or winter, and after 6 o'clock was the agreed time for winter and after 8 o'clock in summer.

The PRESIDENT : Then we agreed to change 25% increase, calling it a war increase. Then Mr. Willett the late President, thought we should go into each individual fee and draw up a minimum scale, so that practitioners should have some idea what to charge—some basis on which to work.

Mr. LEPPER : You can't force those who are not members of the Association to charge these fees. The man who is not a member can charge what he likes.

The PRESIDENT : I think most practitioners are members.

Mr. J. WILLETT : The thing is to point out the fact to non-members that we are dealing with fees, and that it is to their benefit to join the Association.

Mr. COLEMAN proposed that a circular should be sent to M.R.C.V.S., advising them of the decision already arrived at, and pointing out the benefit to be derived from associating with members of the Association.

Mr. J. WILLETT supported Mr. Coleman's proposition

and considered that the circular should be sent to all members of the profession in their area.

Major TAYLOR: A thing like this ought to be controlled by the R.C.V.S. for the whole of the practitioners in the kingdom. It is a thing the Royal College ought to take in hand for it affects the whole profession.

Mr. J. WILLETT: It devolves on the National in a way.

Major TAYLOR: It ought not to. I was President of the Master Farriers' Association in the Midlands. They drew up an elaborate scale of fixed fees. It worked for a short time but eventually fizzled out because so many men charged what they liked.

The PRESIDENT: I am President of the Master Farriers' Association round here. We have put up the fees four times and have had no trouble.

The meeting unanimously agreed to have copies of these fees sent to the M.R.C.V.S. in Berks., Bucks., Oxfordshire, Gloucestershire, Wiltshire and Hampshire. It was also decided to send a copy to the National V.M.A.

The meeting passed a resolution to the effect that an additional fee be charged for each animal examined and also for consultations by letter or telephone.

#### RESOLUTION *re* MILK BILL.

On the proposition of the President the following resolution was agreed to: That the members of the Royal Counties Veterinary Medical Association pray that the Council of the R.C.V.S. take steps to protect the interests of veterinary practitioners in any appointments made under Bills that may be brought forward relating to milk, dairies and the inspection of cows, and so prevent such appointments passing into the hands of men who are not members of the R.C.V.S.

The following three representatives were elected to the Council of National Veterinary Association: The President, Mr. Pauer, Mr. Hancock and Mr. Coleman.

*Election of Members.* The following gentlemen were elected members of the Royal Counties Veterinary Association: Mr. P. LLOYD, proposed by the President; Mr. W. S. KING, proposed by Mr. J. Willett; and Mr. R. I. COLEMAN, proposed by hon. secretary.

*Balance Sheet.* Mr. J. Willett, hon. Treasurer, presented the balance sheet and said they have not so much balance in the bank as last year. Many members were still absent and he would like to have brought the past subscription up to date. But the President thought the matter might be left for a time.

The Treasurer was requested to write to two gentlemen who had not paid their entrance fees nor their subscription, pointing out to them that if these were not paid within six months the Association would be obliged to delete their names.

The financial statement was then adopted.

The Secretary regretted that in the list of names he omitted to give those of Major Simpson, Maidenhead; Mr. A. W. Hancock, Uxbridge; and Mr. F. H. W. Cundell, Swindon.

[The President's address appeared last week, p. 300]

Mr. J. WILLETT proposed a hearty vote of thanks to the President for the able manner in which he had dealt with the different problems connected with the profession. He thought they were all in cordial agreement with the views he had voiced. (The vote of thanks was seconded and carried with great cordiality.)

In acknowledgement the President said the only vote of thanks he wanted was for them to do all in their power to further the interests of the profession.

#### DINNER.

After the meeting the company sat down to dinner and were joined by a number of guests, including the Mayor, Alderman S. Hayward; Mr. E. M. Sturges, (Hon. Sec. of Garth Hunt); Col. Baldrey, C.M.G.; Messrs. J. Lousley, (Chairman of Berks., Bucks. and

Oxon Dairy Farmers' Assoc.); T. Chettle, O. Dixon, W. J. Cumber (Central Chamber of Agriculture and Milk Producers' Council), and Major Taylor.

It was regretted that the following were unavoidably prevented from attending:—Mr. W. A. Mount, M.P., Mr. Cecil Aldin, M.F.H. and Prof. J. Penberthy who was indisposed.

The PRESIDENT, Mr. G. P. Male, was in the Chair. The toast of the King having been proposed by the Chairman, Mr. Coleman gave the toast of the "Imperial Forces" and referred to the allied service's magnificent efforts in protecting the country in her hour of peril.

Col. BALDREY, R.A.V.C., responded.

Mr. Job LOUSLEY proposed the toast of "The Veterinary Profession," which, he said, stood higher today than ever before. He saw no fear of the motor tractor ever superseding horses. A great deal has yet to be done in the direction of increased research in veterinary work, and facilities should be granted and money found by the government, to carry out this research. He wished the profession every possible success, and concluded by coupling the toast with the name of Mr. Slocock.

Mr. SLOCOCK said he thought they should be given more chances in the scientific world than they had been given in the past. He pointed out how they were ridding the country of pleuro-pneumonia and rabies. Their profession had to be viewed from two different standpoints, the point from which others saw them and the point from which they saw themselves. He was, to some extent, responding for the Council of the R.C.V.S., and he referred to the vast amount of beneficial work carried through at the meetings of that Council, who were working for the good of the profession. But the Council was not what it should be. It did what it ought to do, and it did its best, but it ought to be composed of representatives of the whole profession. That rested—not with the members of the Council, but with the men who sent the members there. He mentioned that the profession numbered rather over 3000 members, but a member could be returned to the Council by 200 votes, and this fact showed that 90% of the profession viewed the election with apathy. It was the profession that wanted waking up.

Mr. E. M. STURGES in a humorous speech proposed "The Royal Counties Veterinary Association." He considered that the veterinary profession was never better represented throughout the length and breadth of the land than it was today.

Responding to the toast, the Chairman said that if everybody realised what the veterinary profession had done and were trying to do as much as Mr. Sturges and Mr. Lousley do, they would get more help from the State and Local authorities. The veterinary profession is bankrupt. They had to sell consols to raise funds to examine their students; and the Colleges were depending absolutely on the fees paid by the students for their education. During the war, the number of students had been very small, so that the Colleges were in a most deplorable condition. And this in a country which boasts the finest stock in the world!\* It had only to be brought to the notice of agriculturists for them to realise that the veterinary profession was bound up very closely with agriculture, and that if they increased the efficiency of the veterinary profession it was all to the benefit of agriculture. Therefore, anything they could do to help forward education or experimental research work was for the common good. He hoped Agriculturists would use their influence in trying to get State aid

\*Since this was said, a two-year-old pedigree bull was sold at Penrith for 4750 gns., and one at Perth for 4000 gns. Others for 3300, and 2600 gns. Two pedigree bull calves 24000 and 4750 gns.

for the veterinary colleges—as every other country did. In this period of reconstruction he hoped some of the money would go into the coffers of the veterinary profession.

Mr. T. W. LEPPER proposed the toast of the Mayor and Corporation of Reading, and said he looked upon Reading as the home of their Association, where they held their annual meetings.

The MAYOR in acknowledgement, said he was not quite such a stranger to their profession as they might imagine, having worked under his father, who was a chemist. Anything the Corporation could do to help the profession they would be only too delighted to do, for they had the greatest confidence in their veterinary surgeons.

Mr. J. WILLETT in a felicitous speech proposed The Guests. He said the Association was honoured by the presence of so many distinguished guests who represented all branches of agriculture. He hoped that when the Milk Bill was framed the Veterinary Surgeon would be given his rightful position.

He coupled with the toast the names of Mr. W. J. Cumber, who was on most of the Committees dealing with this milk question, and was also on the Council of the Shire Horse Society, and of Mr. T. Chettle, a noted breeder of Berkshire Pigs and Secretary of the Dairy Farmers Association.

Mr. W. J. CUMBER responding, said the authorities who demanded pure milk should be very careful in their actions, and should not drive the milk entirely off the market. The authorities should send round to the farmers men in whom they could place confidence; otherwise they would seriously curtail the production of milk in the country. If the veterinary profession had not the necessary financial means for developing research work in the future, it was the duty of the government to provide that money, and thus ensure the pure milk supply for the consuming public. No one was more keen than he to see the tuberculous cow removed from the field of milk production, but there was such a prevalence of tuberculous cows that it was a matter which called for great care. These cows were not to be ruled out wholesale, as some members of the medical profession advocated, otherwise there would not be nearly sufficient milk for the public. He hoped the day was not far distant when instead of many of their cows reacting to the test, as they do to-day, it would be a rare occurrence. That could only be brought about as a result of very careful work between the veterinary surgeons and the farmers. They must be very careful in future not to be led into very dangerous paths by men who were faddists.

Mr. T. CHETTLE, who also responded, said that the Dairy and Cow Shed Order gave a good deal of power to the medical Officer of Health. He thought the Medical Officer of health went out of his sphere when he touched animals. The legislature should give to the veterinary surgeon more influence over the management of the dairy herds, in the way of cow sheds and so forth. People had gone mad in regard to the proportion of butter fat, but he believed in clean milk from a healthy animal, irrespective of the proportion of butter fat. Many a farmer had been condemned, fined and branded as a criminal in this connection, irrespective of the fact that there were plenty of cows giving milk below the standard named.

As agriculturists they were much indebted to the veterinary profession, who often saved them from serious losses.

An excellent musical programme was provided.

J. C. COLEMAN, Hon. Sec.

## DERBYSHIRE VETERINARY ASSOCIATION.

[NATIONAL V.M.A.—NORTHERN BRANCH.]

A Special Meeting was held at Derby on Friday February 21st. The President Mr. A. Levie occupied the chair, and there were also present: Messrs. Howe, Wirksworth; White, Castle Donnington; Marrison, Bakewell; H. Fairer, Derby; T. Abell, Derby; Heather, Sandiacre; Aulton, Tutbury; T. H. L. Duckworth, Ashbourne; Hawksworth, Etwell; and F. Prince, Hon. Sec., Ashbourne.

The PRESIDENT said he hoped they would excuse him calling a special meeting at such a busy season, but there were matters to be dealt with which ought not to be deferred, and he thought they might employ their time as profitably as by attending to their ordinary business. They were now, like other professions and trades, passing through a very serious crisis, and it was up to them to grasp the opportunity that now presented itself if they were to move forward as they hoped to do. If the opportunity were neglected, it might never come their way again. The agenda contained several items of importance and he intended to refer to them briefly and then invite the meeting to come to a decision upon them. He trusted that they would be unanimous, because unity of purpose was all important at this juncture, and unless they were all of one mind, the goal before them would never be reached.

The first question was the presence at agricultural shows of vendors of veterinary medicines and surgical appliances. It was discussed at their last meeting, but he was not satisfied with what was done on that occasion. He suggested that after coming to a unanimous agreement among themselves they should take the matter up with the Secretaries of the various agricultural shows in Derbyshire and the adjoining counties, making it clear to them that unless they were prepared to cease letting stalls or stands to quacks, members of the veterinary profession would withdraw their services. He further asked his fellow practitioners, in case agricultural societies failed to satisfy them in that respect, to resign all connection with such societies by way of protest. Let them all resign *en bloc* and he believed their protest would then be effective.

The next item related to veterinary surgeons attending agricultural shows professionally. He asked the meeting to support him in the suggestion that they should endeavour to persuade the whole of the profession not to accept any office, even if they were paid, under any agricultural society that allowed quacks to have stands at their shows. He thought they had the matter entirely in their own hands, but they must all be united in their determination to carry their point. The vendor of quack medicines was the most destructive agent they had to fight. A quack firm often sold as much medicine in a few hours at a show as a veterinary surgeon sold in a whole week, and it was not fair either to them as a profession or to their clients.

Often when a veterinary surgeon was called in to a case he found that some quack remedy had been applied in vain, and he was handicapped by not knowing what that particular medicine was which had to be counteracted. It was a national question, and that was why he thought they had a right to expect assistance in their crusade from veterinary surgeons all over the country. They were strong enough in Derbyshire to form the nucleus of a body of veterinary surgeons quite capable of dealing a staggering blow to the vendors of quack medicines.

The next question was that of local authorities and mileage, which was one of great importance to them. As veterinary surgeons, they were not recognised by local authorities as they ought to be, and they were often asked to do work at a lower rate than was paid to the

ordinary tradesman, and he put that down to the fact that they were too frequently divided in their counsels.

Item No. 4 related to the fees allowed to veterinary surgeons by Insurance Companies. Some companies were prepared to pay the 10/6 which veterinary surgeons asked for an examination, but others would not do so if they could help it. In proof of that, he mentioned a recent experience, when he was asked to travel six or seven miles to examine a horse by a company whose maximum fee was 4/-. Was it reasonable to expect a professional man to put his other work aside and go that distance for a paltry 4/-? He wrote to the company saying he should require the full fee, and a few days later they replied that they would not need his services, as they had made other arrangements for the examination of this horse. He would leave the meeting to form their own conclusions as to what must have happened.

The fifth item was, "Petrol for veterinary surgeons at cost price." They were large consumers of petrol, many of them as much as 600 gallons a year and even more, and they used it in the pursuit of a noble profession. Yet, whilst their next door neighbour, if he happened to be a grocer or a draper, got his petrol at cost price, veterinary surgeons were not allowed that privilege. He suggested that they should approach the Government department responsible for the control of the petrol supply and get that altered. A tradesman could buy his petrol today at 2/10½ per gallon whilst a veterinary surgeon had to pay 3/3½. Why should a veterinary surgeon be compelled to pay 5d. a gallon more than other people? It was most unjust, and ought to be remedied, but that again could only be done by the whole profession showing a united front.

Item No. 6. was perhaps the crux of the whole situation, and it was, "The advisability of forming a union to strengthen our position as practitioners in relation to representation on public bodies." That was where want of unity had done them most harm. It was no use blaming local authorities for anything that happened; it was the veterinary surgeons own fault for not being represented on those bodies in order to see that the profession secured proper recognition. He urged them to unite with other veterinary societies in achieving their object, and thus gain their rights whilst the country was being re-constructed. They had no representation in parliament, which was scarcely creditable to a body of professional men three thousand strong. Surely they were entitled to some voice in the making of the laws, and it was because they had been left in the cold in the past that they were obliged to suffer so many injustices to-day.

He attributed most of their troubles as a profession to the fact that they were not properly represented on public bodies, and the blame for that lay very largely at their own doors. He looked to Derbyshire to take the lead in this matter and throw its tentacles out until they caught all the other societies in their grasp. When every other society in the kingdom came to Derbyshire's way of thinking the profession would be able to move forward with irresistible force.

Discussion followed, and eventually the following resolutions were carried unanimously:—

(1) Proposed by Mr. Heather and seconded by Mr. Abell, "That veterinary surgeons refuse to act in a professional capacity at Live Stock shows where vendors of animal medicines and surgical appliances are allowed to have stands for the purpose of exhibiting or offering such articles for sale";

(2) Proposed by Mr. Aulton and seconded by Mr. Duckworth, "That veterinary surgeons attending officially at shows shall receive a fee";

(3) Proposed by Mr. Harrison and seconded by Mr. Duckworth, "That this Society approach Local Authorities with a view to their increasing the present fee to a

minimum of 10/6 for an inspection and 9d. for every mile actually travelled";

(4) Proposed by Mr. Heather and seconded by Mr. Fairer, "That the Secretary be instructed to write to the Petrol Control Committee requesting that veterinary surgeons be supplied with petrol at the same rate as that charged to the trade";

(5) Proposed by Mr. Duckworth and seconded by Mr. Heather, "That this Society considers advisable the formation of a Union to strengthen our position as practitioners by securing representation in Parliament and upon County Councils, Town Councils and other local administrative bodies: and also to ensure that we are suitably represented on the Council of the Royal College of Veterinary Surgeons".

The meeting concluded with the usual votes of thanks.

F. T. PRINCE, Hon. Sec.

VETERINARY AND COMPARATIVE OPHTHALMOLOGY. By Dr. EUGENE NICOLAS. Translated, edited and enlarged by HENRY GRAY, M.R.C.V.S. Cr. 8vo., pp. xvi. + 598, including 20 p. Index, 225 figures in the text. 15s. net. Postage 6d. H. & W. Brown, 20 Fulham Road, London, S.W. 8.

Mr. Henry Gray, M.R.C.V.S., deserves the gratitude and congratulations of the veterinary profession in the English speaking world for having translated, edited, and largely amplified the excellent work of Dr. Eugène Nicolas, a French veterinarian, on veterinary and comparative ophthalmology, in the form of a neat and handy volume of 600 pages.

The treatise supplies a long felt want, as it is the first one in the English language dealing exhaustively with the affections of the eye and its appendages from a veterinary and comparative point of view.

It includes all the up-to-date knowledge on veterinary and human ophthalmology and is arranged in chapters as follows:—

General remarks on the anatomy of the eye: The eye from an optical point of view: Method of examination of the eye: Ophthalmoscopic examination of a normal eye: The conjunctiva: The sclera and cornea: The uveal tract: The retina and optic nerve: The crystalline lens: The vitreous humour: Glaucomatous affections: The orbit: The eyelids: The lacrimal apparatus: Motor apparatus: Ocular therapeutics and formulary.

The French regulations concerning the affections of the eye in connection with returnable vices are also given.

The anatomy of each part of the eye is fully described before referring to its lesions, thus avoiding the wearisome revision of the anatomy of the eye *en bloc*, and keeping the structure of the part clearly before the mind at the required moment.

The sections dealing with the examination of the eye, cataracts, opacities of the cornea, and affections of the uveal tract, including a long article on recurrent ophthalmia; will be particularly welcomed by clinicians, as they contain more than is commonly known on these practical subjects.

A knowledge of optics is necessary to appreciate the chapter on the "Eye from an optical point of view."

The chapter on therapeutics and formulary contains the latest therapeutic agents and formulae recommended for the various diseases of the eye. All the ophthalmic surgical operations are described in detail. The large number of references and quotations in the text reveal great industry and painstaking on the part of the translator.

The work is profusely illustrated with diagrams and drawings but the coloured plates printed in France and intended for insertion had to be omitted owing to the outbreak of the war.

The captious critic could doubtless find faults in the book, but they are so insignificant compared with its praiseworthy features that they may be ignored. There are several slight errata which are pointed out in a list at the end of the volume.

It is pleasing to note that the work is dedicated to the memory of the late Mr. William Hunting who took such a keen interest in clinical veterinary practice, and endeared himself so much to his *confrères* by his many admirable qualities

J. J. O'C.

#### THE COUNCIL OF THE R.C.V.S AND THE COMING ELECTION.

To the Editor of "The Veterinary Record."

Dear Sir,—I am today in receipt of your issue under date of 28th, Dec, containing report of the meeting of Royal Counties V.M.A. with its discussions on "After-War Problems" in which is embodied a criticism of the present council of the R.C.V.S.

I feel confident this is a matter which will evoke widespread interest amongst the members of our profession and we owe the President of the R.C.V.M.A. a vote of thanks for his timely pert, and pointed remarks on a subject which must have been on the thoughts of many who have been following the happenings at 10, Red Lion Square during the past four years.

Take the conduct of the members who constitute the Registration Committee. What right had they as our representatives to absent themselves from the meetings and neglect the proper conduct of our affairs? There were but two occasions a quorum present out of fourteen meetings, a downright scandal, and amounted to pure persecution of those members involved in the cases that came up for their consideration. If any member of the Registration Committee was granted a temporary commission in the A.V.C. why did he not resign his seat on the Council "for duration"? The profession would have thought none the less of him if he had, seeing one of the conditions of his Army appointment was that he devote the whole of his attention to the duties of his office. Again, the "stay-at-homes" pleaded over-work. More the reason they should have resigned also, than be a non-effective member of a body and hinder the administration of its work. Amongst some of the views expressed at the discussion were:—

- 1 Some members of Council are head and shoulders above others.
- 2 New and vigorous blood is wanted on the Council.
- 3 The Schools are over represented, and rule the profession.
- 4 The Council has no interest in things nearest to heart of the general practitioner.

Taking these paragraphs in rotation; my views are that:—

1 Some members are head and shoulders above others and all credit to them, pity that we had not a few more such gifted men on the Council. I bow to no member, in my admiration for the untiring energy, zeal and devotion to duty of our present President and his few worthy compatriots. The loss of efficiency is not theirs but rests with the inert "remainder."

2 New and vigorous blood is decidedly required on the Council. Let the members wake up and take more interest in the elections of the council, review the work done by the present councilmen, and the attendance-roll statistics, and let the various associations for the coming election put forward a candidate, and if successful at the election, provide him with a list of their grievances for his information and necessary action. I can enumerate half-a-dozen capable men north of the Tweed who

would be new and vigorous blood and at whose hands all matters pertaining to the welfare of the profession would be safe; at any rate they could be trusted to help, not hinder, the members who are "head and shoulders above the others."

3 That the schools are over represented; I don't agree. There are only five members of the present council connected with the schools, and with the many new difficulties that lie in front of our "budding" veterinarians and their course of training, the call is for better representation of the schools on our council.

4 The members of the profession generally have the remedy in their own hands, and if the association adopt the procedure I indicate in my answer to second paragraph—nominate a general practitioner or veterinary inspectors who by dint of sheer ability, hard work and business acumen as private practitioners knew what it was to "paddle their own canoe" to their higher state of officialdom, they may take the place of the many "dud" members now on the council.

In conclusion, we must have the Royal Army Veterinary Corps and the Board of Agriculture represented on the council, and for these representatives we have not far to look.

With reference to men who have been in A.V.C. ranks during the war, and the probability of many ex-A.V.C. sergeants being dumped down throughout the country upon general demobilisation, it is to be sincerely hoped that the Council will make ample provision for dealing with them in their gratuitous advice on ailments and administration of their "pet" stock remedies.

I may say, that amongst the many subjects placed on the curriculum for instruction of N.C.O.'s and men, awaiting demobilization here, is veterinary science. But I hold out no fear from the opposition of any scholars in this class, with the knowledge imparted to them by the lecturer. On the other hand, it is God help the stock owners who are tempted to trust the value of their patients in the hands of such "wise acres" demobilized.

I would repeat. Let the members of the profession wake up:—see to reconstruction of the council and their better representation. Let us drop the "duds," and those who never show any initiative in the proceedings, but when a lead is given them they have always much grumbling and "playing to the gallery"—all to no purpose.—I am, Sir, Yours faithfully,

With the W. GARDNER, M.R.C.V.S.  
Egyptian E. Forces, Jan. 27th.

[The Registration Committee is the whole Council. This is a safeguard to the individual member, but makes the necessary quorum two thirds of the members—twenty-two: and at least three-fourths—(seventeen) of these must vote on the question.]

#### THE CONTROL OF CONTAGIOUS DISEASES OF ANIMALS.

Sir,—Mr. Davis's letter, and that of "non subscriber" in your issue of Feb'y, 22nd., refer very much to the same subject—the question of Veterinary Inspectors.

Every practitioner knows that under its present system the Board of Agriculture has not the full-hearted support from the bulk of practitioners that it should have. The present system of local Inspectorship is not getting the results it should, and never will be effectual. What you refer to as "clinical errors" and what may be described as such, abound.

I agree with "non-subscriber"—that each practitioner should be an Inspector for his own practice: or failing this, that whole-time Inspectors should be appointed, each Inspector being allotted a certain area, in which he should carry out all Inspections: and I believe if

practical, tactful men were chosen for this purpose, that the Board of Agriculture would be surprised at the support it would get from both Veterinary Surgeons and Agriculturists, and also at the results.

If Veterinary Surgeons are to act as Inspectors under the Milk Act something of this sort will have to be done, or affairs will be more chaotic than ever in the profession, and there will be a considerable further falling off in the Milk supply—which, of course, doesn't directly concern us. Dairy farmers in my neighbourhood are not averse to inspection by practical men, but are up against incompetent Inspectors, and Veterinary Inspectors who call and cast aspersions on their Veterinary attendant. Many have already "got the wind up" in view of the coming Act, and say that rather than submit to it they will sell out, and one can't blame them.

I think the profession must now go right ahead or take permanently a back seat.

What a splendid opportunity the present time offers to such a man as Sir Stewart Stockman or other prominent members to re-organise the whole profession, not only for its own good but for that of the State, and at the same time do away with all the present discontent and apathy in the profession. The R.C.V.S., I am afraid, is beyond hope for that purpose.—Yours truly,

Feb. 24th.

COUNTRY PRACTITIONER.

#### THE CUMBERLAND ETHICAL CODE.

Sir,—In your last issue, some rules were set out suggested by nine Cumberland practitioners as a guide for professional conduct as between the members of a proposed federation of practitioners. These gentlemen are to be congratulated on coming to an understanding. But one of their rules was that no member should serve a new client unless the latter first wrote to his former V.S. to acquaint him with the change; and the newly employed V.S. also had to write to the same effect.

Now I do not see why this procedure is either necessary or advisable. It is a free country still, and a client has a perfect right to employ whoever he likes. If a new client came to me with an animal which had not been just previously in veterinary hands, I should not consider it necessary to ask any questions about his former V.S. If a client came to me with an animal which had been in other veterinary hands just previously, I should consider it was up to me to make sure, before taking on the case, that the other V.S. would not be employed again on it; but it would not be necessary to write a lot of letters to find that out.

As it stands, the Cumberland practitioners' ruling suggests that an established man is to have an advantage over a newcomer. Every client the newcomer got would be supposed to write to his former V.S. to explain that he had finished with him. I do not intend that any such ruling shall handicap me when I am demobilised, after the sacrifice of 4½ years' military service, and I am not likely to buy a practice, because too much is being asked for "goodwill," which I consider is worth little in the present state of industrial and agricultural uncertainty.

I think the Cumberland men have gone a little too far in this matter, but a discussion on the subject in your columns might do some good.—Yours truly,

TEMPORARY BLIGHTER.

#### The R.A.V.C. Comforts Fund.

Dear Sir,—May we ask you again to print in *The Record* the latest subscriptions to the R.A.V.C. Comforts Fund.

We are once more greatly indebted to Lieut.-Colonel F. C. Stratton for his ever-ready help, which began in

1914 and has continued up to now. With the help of his friends in the Scottish Command—of whom I enclose a list—he has sent us the very useful sum of £30.

We are also most grateful to Lieut.-Col. K. M'L. McKenzie, D.S.O., for the sum he sent us from France, and to all those who have again contributed money and woollen goods.—Yours faithfully,

E. A. BLENKINSOP.

#### Danger of Basic Slag to Stock.

A correspondent writes in *The Farmers' Gazette*:—

Sir,—I cannot agree with your reply in your issue of January 4th, as to there being no danger in grazing live stock on land top-dressed with basic slag immediately after its application. It certainly is not the case with sheep, and I consider it in the highest degree dangerous to allow sheep to graze on land top-dressed with basic slag until rain or dew has washed it off the herbage.

Two years ago after top-dressing a field with basic slag, 5 cwt. to Irish acre, the gate between it and adjoining field, where some black-faced horny ewes were grazing, was carelessly left open for the night, and some of them were found in the dressed field next morning. They were at once removed, but in the following three days two of them died, and a third a couple of days

after. The cause of death was the same in each case, basic slag impacted into a lump in the intestines, and acute inflammation resulting therefrom.—Yours, etc.,

Stradbally, Queen's Co.

JOHN W. YOUNG.

[We should prefer to call this the danger of an open gate.]

### The Army Mare Scheme.

Before some Cheshire farmers, recently, a circular letter from the Board of Agriculture was read regarding the demobilisation of Army horses, and offering to lend them to farmers to encourage the breeding of horses of artillery type. A mare will be placed out for breeding purposes with a custodian at an annual rental of £2, and she will be allowed to remain in his possession so long as the prescribed conditions are observed. The rent is to be payable in advance, and the first payment is due on the day on which the mare is received by the custodian and shall be paid within fourteen days of that date. In subsequent years, the rent shall be payable on April 1st.

A mare must at all times be properly cared for by the custodian, used only for reasonable work and kept in his possession. The Board and the War Office have a lieu on the progeny of a mare when three years old at £50, and no progeny can be sold without the permission of the Board until October 1st in the year in which it is a three-year-old. A custodian may, however, at any time, claim exemption from this condition on payment to the Board of a forfeit of £10.

### ARMY VETERINARY SERVICE

Buckingham Palace, Mar. 1.

The King held an Investiture in the Ball Room of the Palace, when the following Officers were severally introduced into the presence of the King. His Majesty then invested them with the Insignia of the respective Divisions of the Orders into which they have been admitted :—

\* \* \* \*

#### THE DISTINGUISHED SERVICE ORDER.

Major Hugh Gibbs, R.A.V.C.

#### ORDER OF THE BRITISH EMPIRE.

The King has been pleased to give orders for the following appointments to the Most Excellent Order of the British Empire, for valuable services rendered in connection with military operations in Mesopotamia. The appointments to date from January 1 :—

\* \* \* \*

O.B.E. (Military Division).

Temp. Capt. J. R. Hewer.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Feb. 28.

#### REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Temp. Lt. A. H. Morris to be temp. Capt. (Feb. 1).

Mar. 4.

Maj. W. C. Lowe, F.R.C.V.S., relinquishes actg. rank of Lt.-Col. (Feb. 13).

The following relinquish their comms. :—Temp. Capt. R. P. Johns, acct. of ill-health (Mar. 5), and retains rank of Capt. ; temp. Hon. Capt. F. Armstrong, on ceasing to be empld. (Feb. 8), and retains hon. rank of Capt.

The War Office announces the following casualty :—  
Capt. J. Bradley, R.A.V.C., attd. R.F.A.

#### TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Feb. 28.

Capt. (temp. Maj., actg. Lt.-Col.), E. W. Parks, O.B.E., to be Maj., and to retain actg. rank of Lt.-Col. (Jan. 12).

Mar. 1.

Maj. J. Abson, D.S.O., F.R.C.V.S., is retired, having attained the age limit (Mar. 2), and retains rank of Maj., with permission to wear the prescribed uniform.

ERRATUM. In our issue of Feb. 1, p. 271, Capt. R. P. Jones, attd. S.A.F.A., was inadvertently placed under heading N.Z.V.C.

### OBITUARY.

W. J. FOREMAN, Leadgate, Co. Durham.

Graduated Lond: Dec, 1894.

Mr. Foreman's death occurred on Feb. 18th, at the age of 46.

"We understand that Mr. Foreman caught cold nearly three weeks since, influenza developed about a week ago, followed by pneumonia, and despite the devoted attention and medical skill, the patient succumbed. In Leadgate especially the sad news called forth expressions of sincere sorrow, for no man was more honoured and esteemed. His genial and kindly disposition and his winning personality endeared him to his numerous friends. In the home circle, the loss is irreparable, as Mr. Foreman was a devoted husband and a loving father who was idolised by his children.

Councillor Foreman was one of the oldest members of the Leadgate U.D.C., first elected 21 ago, when the late Mr. Thos. Foreman retired from the Council, and his son—then a very young man—was induced to come forward, with the result that he headed the poll. In due course he was called to the chair—just at the time that the new Council premises were opened—and in honour of the occasion he and Mrs. Foreman entertained the members of the Council, the officials etc. Councillor Foreman occupied the chair for three years with every satisfaction to those concerned, and also took his seat upon the bench. He was elected Chairman of the Leadgate Tribunal, and discharged the responsible duties with tact and impartiality. He took keen interest in and acted as treasurer to the local War Savings Association. He was a staunch Churchman, and a Conservative in politics. A few years since he was chosen to follow his late respected father as people's warden at St. Ives Church, Leadgate—a position which he filled with conspicuous ability. In fact in everything Mr. Foreman took in hand he was thorough and conscientious. A man of sterling and upright character, whose word was his bond, he was rightly looked upon as possessing all the attributes that go to make up a typical English gentleman.

In his younger days Mr. Foreman was a keen athlete. He captained the Leadgate Park football team at a time when a very strong side achieved some notable victories. The defence of Councillor Foreman and his brother Frank, at back, was a feature in those days. Later on he became president of the club. He was also a great lover of tennis. He was the first president of the Blackhill and District Institutes Billiard Tournament. His was a busy, well-spent life which has ended all too quickly. In addition to keeping his large practice going he found time to serve his fellow men in many valuable ways, and this he did cheerfully and willingly."

G. S. HEATLEY, East Dulwich, S.E.

Edin: Jan. 1883.

Mr. Heatley died Feb. 24th, aged 70.

#### The Late Mr. Oxenham.

On Feb. 10th. the whole of the Aberdare Valley was shocked to hear of the sudden death of Mr. Oxenham, of Mountain Ash. Whilst in pursuance of his ordinary occupation at Cwm-dare Collieries a sudden seizure felled him to the ground, and he passed away in a few moments. Mr. Oxenham was the veterinary surgeon to Messrs. Nixons Navigation Colliery and Bwlfi Merthyr Dare Colliery Co.—a position that he had held for a number of years. During that time his long experience in purchasing the right stamp of colliery horse was of great value to both companies. As a man amongst men he was held in high esteem, and whether it was the pit proprietor's horse, the collier's dog, or the hawker's pony, he was ever ready to give his services in both senses of the word. The doctor, as he was affectionately called by his friends, was a real pal. In sport he was one of the best, and support—monetary and advisory—was always tendered. Local horse show committee know this only too well, and the Aberdare societies will feel his death very severely. In politics he was broad-minded perhaps leaning towards Conservatism, but he was a rare one for having the best man, just as he was for the best horse—no matter what colour. He was a brother of the Freemason craft of St. Davids Lodge Aberdare. He was born in Aberdare 46 years ago, was a pupil of Mr. Temple, of Aberdare, and took his degree at Edinburgh College. He leaves a sorrowing widow, one son, and one daughter. His son, Ivor, is at Brecon College.

HARRY BLAKEWAY, B.Sc., M.S. LOND., F.R.C.S. ENG.,  
Resident Assist. Surgeon, St. Bartholomew's Hosp.

Influenzal pneumonia has claimed another member of the staff of St. Bartholomew's Hospital. Harry Blakeway was the son of James Blakeway, of Stourbridge, and was educated in his native town before coming up to a brilliant career in London University. He started in preparing himself for a medical career by taking a science degree in 1905. After carrying off most of the prizes and scholarships available to students at St. Bartholomew's Hospital, he qualified M.B., B.S. in 1908 and took the highest distinctions in surgery at the University and at the Royal College of Surgeons of England two years later. In conformity with a usual practice, he became house surgeon to the Great Northern Central Hospital before returning to his own school, where he was successively house surgeon, demonstrator of anatomy, surgical registrar, temporary assistant surgeon, finally occupying the emergency war-time post of resident assistant surgeon. Of the occupancy of this post a colleague (R.M.V.) writes:—

"During the last years of Blakeway's life he was one of those to whose lot it fell to remain out of the hustle and turmoil and interest of the war, and he laboured unceasingly and untiringly at the less glorious but none the less essential work in the school of his adoption as resident assistant surgeon. Much of the weight of the civilian practice of the hospital fell on his shoulders and he worked nobly and well to maintain the high standards of the past."

This appointment left him but little time to work at the surgical diseases of children and the treatment of hernia, subjects in which he took peculiar interest, but he was surgeon in charge of out-patients at Victoria Hospital for Children and assistant surgeon to the City

of London Truss Society. Blakeway's signed writings are limited to a number of brief but well-digested papers on surgical topics, including his Hunterian Lecture on the Operative Treatment of Cleft Palate, delivered in 1915; but he was widely read in surgical literature, and was a valued author of unsigned reviews in our columns.

Although for Blakeway work was its own reward and he laboured for no other, his friends must regret that he did not live to reap the benefit of years of unending toil. In him surgery has lost a straight and earnest disciple, and his colleagues mourn a good and genial friend. He leaves a widow and three children, to whom we tender our heartfelt sympathy.—*The Lancet*.

[Second son of Mr. James Blakeway, M.R.C.V.S., of Stourbridge.]

Many South Africans in this country will have been shocked at the tragic fate of young Ridlington, who got "caught up" in the tapes at the start of a race in Johannesburg, and was thrown and killed. One who knew the boy and his family well tells me that Ridlington was one of the finest jockeys under the Southern Cross. His father is a well-known trainer and sporting journalist—editor of the "Licensed Victuallers' Gazette," I believe, in Johannesburg—and the poor boy was a grandson of Mr. A. Ridlington (of Ramsey, Hunts), a prominent veterinary surgeon. The youngster was both clever and clean, and was a familiar figure in the saddle all over the country.

#### Personal.

Mr. SIDNEY VILLAR, who was for some time seriously ill, was able, a fortnight ago, to leave hospital at Twyford, and is now convalescent at Osborne, Isle of Wight.

Mr. RICHARD SAM REYNOLDS, M.R.C.V.S., of Knotty Ash, near Liverpool, and of Blidworth, Nottingham, one of the early members of the Shire Horse Society and of the Royal Lancashire Horse Society, a judge of draught horses at the principal shows in England, left £25,643.

At a meeting of the Contagious Diseases (Animals) Committee, Hunts County Council, Capt. W. K. TOWNSON was appointed Veterinary Inspector, Norman Cross Division, Hunts, in place of Mr. J. Mackinder, resigned.

#### RESTORATION TO THE PHARMACOPOEIA OF PREPARATIONS CONTAINING SUGAR, GLYCERIN, AND CERTAIN OILS AND FATS.

"The Acting Registrar of the General Medical Council has favoured us with a copy of the subjoined official intimation:—

At its meeting on February 24th, 1919, the Executive Committee of this Council considered the advisability of withdrawing the temporary alterations in the British Pharmacopœia, published in the *Gazette* of July 27th, 1917, and March 29th, 1918, arising out of the scarcity during the war of sugar, glycerin, and certain oils and fats, and adopted the following resolution:—

"That the Executive Committee, on behalf of the Council, order and direct that on and after April 30, 1919, the British Pharmacopœia, 1914, shall be altered and amended by revoking and withdrawing the alterations and amendments made and published in the *Gazette* of July 27, 1917, and March 29, 1918, and that formal intimation of such revocation and withdrawal be published, according to law, in the *Gazettes* of London, Edinburgh, and Dublin on April 30, 1919."

*The Pharmaceutical Journal*

## CONCERNING A BYE-LAW.

To the Editor of "The Veterinary Record."

Dear Sir,—I send you the following case for the information of the profession.

Mr. X satisfactorily attended the various classes in the Dublin College in 1918 for the Class B examination with the exception of four weeks during which he was absent on account of illness prior to his examination, which he was unable to sit for.

Private circumstances now compel Mr. X to attend the Glasgow College. He voluntarily rejoined College in January 1919 so as to get in 20 weeks more study for his B examination in July—a total of 46 weeks.

At the last meeting of the Examination Committee of the Council (at which I was unable to be present) this student was refused permission to sit for his B examination in July because he does not fulfil the requirements of Bye-law 62 which says he must have satisfactorily attended "for one session (30 weeks) at one of the affiliated Veterinary Schools." He will have put in 26 weeks in Dublin and 20 weeks in Glasgow yet he cannot sit for his examination because he has not put in 30 weeks at one College.

My own view is that one is meant to take the spirit and not the letter of this Bye-law.

Now, sir, I am not in sympathy at all with those who have recently been hurling abuse at members of Council, but a decision such as the above does make one think. It would be merely silly, if it were not such an injustice to the student.

If some Members of Council take such narrow-minded and petty views on details, how is the Council, as a whole, to deal with larger and more important matters, concerning the welfare of the profession, in the right spirit?—Yours faithfully,

S. H. GAIGER, F.R.C.V.S.

Glasgow Veterinary College, 5th March.

## Prosecution by the R.C.V.S.

At Halesworth (Suffolk) Petty Sessions, 27th February, 1919, Charles M. Smith, of Wrentham, was summoned for unlawfully using the description "veterinary surgeon."

Mr. Geoffrey Bracey, solicitor, on behalf of Messrs. Angell and Foward, solicitors, Beccles, appeared to prosecute for the Royal College of Veterinary Surgeons. Mr. Bracey stated that the offence consisted in signing the necessary document for the removal of three dogs from the infected rabies area of Cornwall and Devon, without legal authority.

Mr. Ernest Cooper, solicitor, of Southwold, appeared for the defendant, and said he had served 12 years with the Yeomanry, and was discharged from the Army owing to his usefulness to the farmers of the neighbourhood. He had assisted his grandfather, who was a veterinary, for several years, and thereby had not the opportunity of passing through the necessary examination of King's College. The Bench imposed a fine of 40s., and costs £4. *East Anglian Daily Times.*

# THE VETERINARY RECORD

A Weekly Journal for the Profession.

FOUNDED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1601.

MARCH 15, 1919.

VOL. XXXI.

## AN ANNIVERSARY: AND A RETROSPECT.

Probably few veterinarians will have noticed that last Saturday was an important anniversary for us. Our first Charter is dated March 8th, 1844; so the profession attained its seventy-fifth birthday last week. This would be a noteworthy landmark under any conditions; and it becomes more so from occurring at such a singular and critical period of our history, and indeed of all history.

Looking back over the three quarters of a century, we have much cause for satisfaction. Considering what we were at the beginning, the difficulties that have confronted us, and the little outside help we have had, the wonder is that we have advanced so far in three generations. Our past progress gives us good hope for the future, however dubious the immediate present may appear.

Just now we hear the profession described as "seething with discontent," and so it is. So, probably, is almost every other section of the nation—if we except professional warriors and the numerous species classed generically as "war profiteers." The present unrest in the veterinary profession is very similar to that which is agitating the whole country, depending upon much the same causes, and developing along analogous lines. Old grievances have become more acute and some new ones arisen; and some parties unfortunately seem to think that all can, somehow, be remedied at once. Tendencies to insist upon individual claims without regarding communal ones, to blame leaders and governments for everything, and to fly to precipitate action, are more or less evident everywhere. We have entered upon a period of transition of which no one can yet either appreciate all the issues or foresee the end; and our profession, like probably every other body, shows some unsteadiness in facing the new conditions.

On the whole, we have a better chance of holding our own in the coming struggle than many other callings. We have a firm legal status which is not likely to be weakened, while we may hope to strengthen it still further by judicious action. We are neither a mushroom industry developed under war conditions, nor a parasitic one dependent upon the luxuries of peace, but a profession with a long record of national service to prove our economic utility. Claims such as these, with good management on our part, should enable us to gain our just ends; while such errors as over-estimating our own strength and importance would be peculiarly dangerous in a profession so small as ours. The men whom we trust to guide our course today should be not only alert and energetic, but also prudent and level-headed; and we all know that the two sets of qualities are not always found in the same individual.

## FRACTURE OF THE NAVICULAR BONE.

Bérrar, in the *Deutsch Tierärztlich Wochenschrift* for 1913, discusses this subject. Fractures of the navicular bone are usually effected in the transverse direction and situated in the neighbourhood of the medial crest. There are predisposing causes, such as prolonged rest, neurectomy, etc.; while the exciting causes are concussions or traumatism. The certain diagnosis can only be established by means of the Röntgen rays; for acute navicular disease and arthritis of the foot present the same symptoms as fracture of the navicular bone. Prognosis is always unfavourable; and the lameness persists even in cases where the fracture is consolidated by a callus.

In twenty five horses destroyed on account of incurable affections of the organs situated in the interior of the hoof, Bérrar found, upon post-mortem examination, four fractures of the navicular bone.

The author advances interesting considerations concerning the genesis of these fractures, basing his arguments upon the function of the bone. The bone is compressed between the second phalanx and the perforans tendon; and all its interior structure is organised to support pressure. This structure resembles a collection of tubes or columns disposed perpendicularly to the two surfaces of pressure. The navicular bone is fixed at its two extremities by a rather complex ligamentous apparatus, and supported by the perforans tendon. Fractures supervene from excessive pressure transmitted by the second phalanx; and the perforans tendon, which is relaxed in certain positions of the limb, may not counteract such pressure sufficiently.—(*Annales de Médecine Vétérinaire*).

## ATOXYL IN THE TREATMENT OF MALIGNANT CATARRHAL FEVER.

Wysmann, in *Schweizer Archiv. für Tierheilkunde* for May 1918, reports in detail fourteen cases of malignant catarrhal fever which he has treated with atoxyl, and also mentions the result which he has previously obtained with the same drug in other cases. The results he has observed have not been uniform. In some cases the atoxyl showed a very rapid curative action; in others, however it produced no benefit.

It must not be forgotten that malignant catarrhal fever is capable of cure, even in grave cases, with other remedies. Wysmann, therefore, concludes by saying that atoxyl is not the ideal remedy in this disease, as its action is neither constant nor regular.—(*La Clinica Veterinaria*).

W. R. C.

# VICTORIA VETERINARY BENEVOLENT FUND (INCORPORATED)

The First meeting of the Council of the Fund since its incorporation was held at 10 Red Lion Square, London, W.C., on Thursday March 6th, 1919, when the following members were present:

Mr. S. H. Slocock (President), in the Chair, Mr. E. Whitley Baker, Mr. G. A. Banham, Sir J. M'Fadyean, Mr. J. W. McIntosh, Mr. E. Alfred West, Mr. J. Willett, Prof. G. H. Wooldridge, Mr. G. Thatcher, Solicitor, and Messrs. P. J. L. Kelland, and F. Bullock, Honorary Secretaries.

Apologies for absence were received from Messrs. Barrett, Bradley, Dawes, Dunstan, Price, Johnstone, Trigger, and Sir Stewart Stockman.

The Minutes of the previous meeting were taken as read and confirmed.

*Incorporation.* The Memorandum and Articles of Association were submitted, together with the certificate of Incorporation of which the following is a copy:—

No. 153010 Certificate of Incorporation. I hereby certify that the Victoria Veterinary Benevolent Fund (the word "Limited" being omitted by Licence of the Board of Trade) is this day Incorporated under the Companies Acts 1908 to 1917, and that the Company is Limited. Given under my hand at London, this sixth day of February, one thousand nine hundred and nineteen.

A. E. TAYLOR,

Assistant Registrar of Joint Stock Companies.  
Fees and Deed Stamps £22.

*Constitution of Council.* The Solicitor reported that in order to complete the preliminaries of incorporation as quickly as possible he had sent in the consents to act as Member of Council from such members as had replied in time, and their names had been registered. It was now necessary formally to co-opt the remaining members of Council whose consents to act had been received since the date of Incorporation. This was authorised under Article 20.

Mr. Banham thereupon proposed, Mr. West seconded, and it was unanimously carried, That the following be co-opted Members of Council: Messrs. E. Whitley Baker, F. W. Garnett, F. L. Gooch, J. Ewing Johnstone, J. McI. McCall, W. J. Mulvey, T. Salusbury Price, A. Spicer, R. C. Trigger and W. Jackson Young.

A further point was raised as to the interpretation of Clause 18 of the Articles, and it was resolved, That an extraordinary meeting of the Members be called for April 10th, to alter the Articles of Association, so as to provide that any Veterinary Medical Association or Society which contributes annually to the Fund a sum of not less than two guineas shall be entitled to nominate a member of Council.

*Secretaryship.* The President requested Mr. Bullock to withdraw during the consideration of this matter. In his absence the President said that in the new circumstances of the Fund as an Incorporated Association, it was in his opinion necessary that a paid official should be appointed. There were certain important duties to be performed under the provisions of the Companies Acts which involved a large increase in the Secretarial work. The books and records of the Fund had to be kept in strict accordance with the law, and annual returns were required to be made under considerable penalties. Mr. Bullock had joined Mr. Kelland as Honorary Secretary two years ago, and he could not speak too highly of the excellent work he had done for the Fund. The number of subscribers had greatly increased, and the amount paid out to recipients had also augmented. The provision of the Stephenson Bequest would also add considerably to the Secretary's

work. He felt that there was no one who was so competent to carry out the duties of the Secretaryship and to see that all the requirements of the law were duly satisfied as Mr. Bullock. He therefore proposed that Mr. Bullock should be elected Secretary to the Fund at a remuneration. He suggested that the amount should be fifty guineas per annum, to include all necessary payments for clerical assistance.

Mr. West seconded the proposition, stating that he associated himself with everything Mr. Slocock had said as to the excellent work Mr. Bullock had done for the Fund.

Sir John M'Fadyean supported the motion, and it was ultimately carried unanimously.

Mr. Bullock was then recalled and informed of the decision. In thanking the Council for the appointment, Mr. Bullock said that the work he had done had been done with pleasure, and that he would have been quite willing to continue it without remuneration, as it was a work undertaken for the benefit of the profession he had the honour to serve. Since, however, the Council wished that the office of secretary should be a paid appointment, and had fixed so generous a remuneration, he promised that in accepting the appointment nothing should be lacking on his part to carry out the duties conscientiously, and he hoped, with increasing success.

*Auditors.* The question of the appointment of Auditors was considered and the secretary was instructed to communicate with Messrs. Woodhouse and Wilkinson, the present Honorary Auditors, to ascertain whether they were willing to offer themselves for re-election and on what terms.

*Appointment of Bankers.* Mr. West proposed, Mr. Banham seconded, and it was resolved "that Barclays Bank Ltd. be appointed the bankers of the Fund, and that they be authorised to honour all cheques signed on behalf of the fund by the President, Treasurer and Secretary."

*Common Seal.* A specimen of the Common Seal was submitted and on the motion of Sir J. M'Fadyean, seconded by Mr. Willett it was unanimously approved.

It was ordered that the Seal be duly affixed to the contract for the purchase of War Loan from the Stephenson Bequest, and also to the necessary transfers of the Invested Funds from the names of the Trustees into that of the Fund.

*Clement Stephenson Bequest.* The question of the management of the Clement Stephenson Fund was raised, and the Solicitor read the terms of the Bequest as follows:—

"The annual income is to be kept separate and distinct from the ordinary income of the Institution and is to be called the "Clement Stephenson Fund," from which the Council of the Fund is empowered to grant relief either in the form of gratuities or fixed periodical allowances to necessitous and deserving widows or families of duly qualified Veterinary Surgeons in the United Kingdom."

The Solicitor pointed out that no provision seemed to be made for any expense of administration to be charged to the Stephenson Fund, and that no grant could be paid to a necessitous member out of that Fund.

It was thereupon decided that all expenses of administration be charged to the general Fund, and that any question of allocating certain of the present grants from the Stephenson Fund be deferred for the time being.

*First General Meeting.* It was resolved on the proposition of Sir J. M'Fadyean, seconded by Mr. McIntosh, that the first General Meeting of the Fund in accordance with the Articles of Association be held on April 10th, at 6 p.m.

*Annual Report.* The Secretaries submitted a draft of the Annual Report, which was duly approved for issue to the Members of the Fund before the Annual Meeting.

*Relief.* A further application was received from Mrs. B. Y., for a grant towards the balance of the cost of her son's equipment as a cadet in the mercantile marine. It was resolved—That a grant of fifteen guineas be made to Mrs. B. Y., from the Clement Stephenson Fund, being the balance required to complete the cost of her son's outfit.

## VETERINARY MEDICAL ASSOCIATION OF IRELAND.

[NATIONAL V.M.A.—IRISH BRANCH.]

A general meeting was held on Friday Nov. 29th, in the Gresham Hotel, Dublin. Prof. J. J. O'Connor, President, occupied the chair and other members present were;—Messrs. Healy, Wilkinson, J. Doyle, W. W. Malone, F. C. Mason, L. M. Magee, Knight, C. M. Griffin, J. H. Norris, J. B. Dunlop, Capt. Winter, and Profs. Craig and Browne.

Apologies were received from:—Messrs. Prentice, Kerr, Mahony, Howard and Holland.

The minutes of the previous meeting which had been circulated were taken as read and signed.

*Correspondence.* The following correspondence was read:—Veterinary Officers V.M.A. and North of Ireland V.M.A.

### REPORT OF COUNCIL. 29th Nov.

A special meeting of Council was held on 13th June 1918 to consider the advisability of opening a subscription list for Mrs. Mettam. After some discussion it was decided to defer action in the matter and that Mr. Watson and Prof. O'Connor should interview a Government Official re a Government Grant.

A meeting of Council was held on the 25th of July 1918, at which it was decided to abandon the general meeting in August for this year.

A meeting of Council was held on the 12th November 1918 at which it was announced that Mr. C. A. Ewing had won the medal awarded to the student gaining the highest aggregate of marks in his Final professional examination, held in the Veterinary College in July 1918. It was directed that two medals be struck and one awarded to this student.

Printing account was passed for payment.

It was directed that the question of defraying part of the expenses of Mr. Howard incurred in attending the Council of the Royal College of Veterinary Surgeons be brought up at the general meeting. In the meantime the various V.M.A. to be again written to for a definite reply to the letters sent them in the earlier part of the year.

The general meeting to be held in the Gresham Hotel at 7 p. m. on the 29th of November, Paper on "Notes on Clinical cases" by Mr. Magee to be printed and circulated with the notices convening the meeting. Reporter to be employed.

Mr. NORRIS proposed, Mr. Wilkinson seconded and it was passed that if notes of the speakers at the general meeting, sent them for revision be not returned within 14 days, the original notes be sent on to the printers for publication.

Prof. CRAIG announced that the Solicitors to the late Mr. Jas. McKenny had written him that the Grant of Administration had been mislaid. Till this is produced nothing could be done with regard to the transfer of Trusteeship.

The CHAIRMAN: Gentlemen—you have learned from the Report of the Council that Mr. Watson and myself were deputed to interview some representatives of the Government to ascertain whether their would be any objection to our approaching Irish M.P. with a view to obtaining their influence in furthering the petition to

the Lords of His Majesty's Treasury for a Civil List pension for Mrs. Mettam. Prior to going holiday in August I tried twice to get Mr. Watson to accompany me but he was so busy he was not able to come. During my absence Prof. Craig, having learned that there would be no objection to such a course of action, made arrangements to have some M.P. including Sir E. Carson, Mr. Devlin, and others interviewed on the matter. Under these circumstances I trust I will be excused for not having the wishes of the Council officially carried out.

Prof. CRAIG gave some information regarding the steps he had taken to interest some prominent Members of Parliament and others in the petition.

The CHAIRMAN: We have now to deal with Mr. Howard's expenses, incurred in travelling to London to attend the Council meetings of the Royal College of Veterinary Surgeons. You know that Mr. Howard has represented the Veterinary Profession in Ireland on the Council for some years.

He went forward as a candidate at the request of the members of this Association—not on his own initiative. He demurred about accepting the honour because he thought the expense would be rather too much for him, but we said we would subscribe towards his expenses, and would not allow him to be too much out of pocket in the matter. Several years have passed now, and we have done nothing towards fulfilling this promise. Mr. Howard has attended most of the meetings during the war-time when the cost of travelling has been enormously increased. On more than one occasion he has expressed his willingness to retire in favour of some other member. When his first term of office expired he was not anxious to go forward again, but our association pressed him to do so, and nominated him for re-election, and he was successful at the poll. I doubt if there is another man in Ireland who would undertake the responsibility of this position, which undoubtedly entails great loss of time and great monetary expenditure, but Mr. Howard is very enthusiastic in veterinary matters, as we have had recent proof of in connection with the grievances of the Veterinary Inspectors. You know he was the first to take up their case and fight it without any prospect of self interest—but on the contrary, with a possible risk of injuring his own interests. It must be understood that we are not conferring any favour on Mr. Howard by contributing towards defraying his expenses; we are only discharging, in a rather belated fashion a debt of honour, and showing some appreciation of his able services on the Council. We should congratulate ourselves on having a man like Mr. Howard who is so popular across the Channel that he can command success at the poll.

We ought not to lose any more time in dealing with the matter.

Mr. NORRIS: I think this question of Mr. Howard's expenses is primarily a matter for this Association, but the other Associations in Ireland have also an interest in it, and we have been endeavouring for some time past to get them to take a practical interest in it. We have heard the letters read from two of the Associations but there is nothing definite in them. I think the only thing we can do to-night is to postpone the matter until we hear definitely from these Associations what they are going to do. In suggesting that, I don't mean that the matter should be allowed to drift very much longer.

Capt. WINTER: Mr. President—as secretary of one of these associations I owe you an apology. The first I heard of this matter was last Monday, as your letters did not reach me when I was away. I immediately got into communication with Mr. Healy and Mr. Mahony. Mr. Mahony unfortunately could not be here to-night, but he is quite willing to stand by anything we do. Our association has not much money, but I think we can get some together. We should not postpone this thing

altogether. We should have a discussion as to what Mr. Howard's probable expenses were and what this Association can do; then we will see what we can do.

The CHAIRMAN: Capt. Winter need not apologise for we do not communicate officially with the Central Association on the subject, knowing that they were willing to subscribe.

Mr. DUNLOP: This matter has come up so often that I think we should decide something now. The question is, is this Association prepared to vote a certain sum or are we as individuals to subscribe?

Prof. CRAIG: I agree with Capt. Winter that this matter should be threshed out now. During the present year it was decided that a contribution should be made to the expenses incurred by Mr. Howard, and it was decided that from the funds of the Association a sum of £10 should be contributed, and that the rest of the money should be obtained partly from the other Associations and partly from the members. Up to the present the members of the other Associations have not come forward, therefore I think we will have to depend on members of this Association to contribute towards the fund. So far as the funds of this Association are concerned by the end of this year we will have exceeded our income by about £30, if we include the £10 contribution to the expenses of Mr. Howard. I would propose that a subscription of 10/- be asked from the various members.

Mr. HEALY: I think if any member of our profession deserves credit it is Mr. Howard. He has done his duty like a man, and I think it behoves every member of the Association to assist in covering his expenses. We have in our small Association the sum of £8 which we will give over to the fund, but I think outside that every member of the profession in Ireland should give a subscription. I hope the voice of this meeting will go forth to the profession in the country, and that they will assist in every way they possibly can.

On the motion of Mr. KNIGHT, seconded by Capt. Winter the following resolution was passed:—"That the members of this Association, also the members of the profession in Ireland, be asked to subscribe a sum of 10/6 towards the expenses incurred by Mr. Howard, of Ennis, as the Irish representative on the council of the Royal College of Veterinary Surgeons; since Mr. Howard only consented to act on the council when a promise was given that a contribution would be made towards his expenses."

Mr. MAGEE: At the last Council meeting we calculated that Mr. Howard's out of pocket expenses alone during the year would come to about £60 for travelling to London, but that does not represent what his full expenses amounted to.

Mr. HEALY: Put us down for £10 from the Central Association.

A number of subscriptions were then handed in.

#### CLINICAL CASES.

By L. M. MAGEE.

(The paper had been printed and circulated to members.)

For the shortcomings of this paper I shall try to console myself with the thought that our President, Professor O'Connor, is, to a certain extent, responsible. He gave me only a few days' notice to get it ready, and as I am slow with the pen I must shift some of the blame on to his shoulders.

The subject which I have chosen is always a popular one at veterinary medical meetings, and probably appeals to members more than any other. Accounts of unusual and interesting cases are expected, and a discussion on several subjects generally follows, from which information and knowledge are often gained.

#### AMPUTATION OF UTERUS—SOW.

While away from home a telephone message came to attend a sow about twelve miles away. As it was late when I returned—and the message did not say that the case was urgent—I put off the visit till next morning. The owner, who was a poor woman, informed me that the sow had given birth to six live young the morning before, and shortly afterwards had put out the whole of her pig-bed. Attempts to return it had failed. The patient lay prostrate and objected to getting up, but she was not blowing. Her ears and legs were rather cold, and she refused her food. It required but a short examination to decide that the return of the uterus was out of the question, as it was dry, stiff and filthy, and that the only chance of saving the sow's life was to amputate the organ.

On hearing this the owner seemed very pleased, and informed me that the night before, when some of her neighbours were in trying to "give her a hand," she told them that when the vet. came he would probably cut it off; but they only laughed at her. She, therefore, told me to "fire away." Having sterilised a scapel and a few strips of calico by boiling, I tied the sow's four legs together with a rope. The uterus was now pulled out as far as possible, and a strong calico ligature tied very tightly around the neck, close to the vulva. To make sure, another was applied in front of this, and the organ was amputated about an inch behind the ligatures. The raw stump was then seared with a red-hot poker before allowing it to slip back into the vagina, and the sow was released. She stood the operation well. A few weeks afterwards I received a letter from the poor woman, in which she said: "Half an hour after you left she took to her food, and being carefully fed, both herself and buns are in excellent health."

Some of the members may remember that about ten years ago, in a paper which I read before the Association, among other cases I recorded a successful one of the same kind which I had with a cow. I have also had failures with the operation, but I hope to refer to these in the course of the discussion, and to some pitfalls to be avoided.

Where the return of the uterus is not possible, and where there is a reasonable chance of success, unless the animal is fat, I think we should never hesitate to perform amputation.

#### INTUSSUSCEPTION

Three years ago I attended a valuable greyhound puppy, nine months old, apparently suffering from acute constipation. He showed no signs of pain, and there was no straining. A dose of castor oil was administered, and frequent enemas of warm soap solution. He was no better next day, and had developed very pronounced jaundice. He was now put on to medicinal paraffin, and the enemas were continued. No improvement occurred, and he died two days later. A *post-mortem* showed that the cause of death was intussusception of the small intestine, and I produce the specimen for inspection.

Last year one of the Ward Union Stag Hunt pups was sent to me suffering from jaundice. He looked miserable; did not seem to be in pain; did not strain, and there was constipation. I associated the jaundice with distemper. Forgetting my previous experience, and not suspecting intussusception, I did not examine the abdomen, and treated the pup on the same lines as the former case. He only lingered for a few days, a *post-mortem* revealed another splendid specimen of invagination of the small bowel, which I also present.

Of six authors whom I have consulted, Hobday is the only one who mentions jaundice as a possible symptom of the condition.

When my friend, Mr. Heney, who has a large dog practice, was once down with me in consultation, I showed him these two specimens, and told him the histories of the cases. He was very interested, and said he had had several fatal cases of jaundice in young dogs, but, like myself, never suspected intussusception. Possibly it may be a commoner cause of jaundice than we think, especially in young dogs.

#### "DOPED."

I had often heard stories of broken-winded horses being "set" by gipsies and low-class horse dealers so that they defied detection at sale, and sometimes remained apparently sound for some days after purchase. But I really didn't believe that the practice commonly known amongst the fraternity as "setting a piper" was possible so that a veterinary surgeon could be deceived. In the summer of 1915 I had a painful awakening to the fact that I was wrong.

My brother-in-law was buying for the Army, and whenever I saw a horse likely to suit him I let him know. A few miles from Dunboyne there is a famous common known as the Moor of Meath, which is frequented by so-called gipsies and tinkers, who deal in screw-horses, donkeys, poultry, etc. I don't think, however, that I have ever seen a genuine gipsy amongst them. While driving across the moor one afternoon I noticed a caravan halted close to the road and three or four horses grazing about a quarter of a mile away. Thinking that possibly there might be a good one amongst them I got out and walked across, but found that they were all screws. As I came back to the road I saw the owner of the caravan coming towards me from the other side of the moor. He was a low-sized, butty man, with a face that was not prepossessing. With a pronounced cockney accent he asked me if I wanted a horse. Having told him what I was looking for, he pointed to a mare that was grazing away at the end of the moor which, he was sure, would suit, and if I was returning that way he would have her ready for me. Saying that I would be back in about an hour, I went on to my case.

On my return he had the mare on the road. She was a nice, six year old bay mare, and having walked and jogged her I thought she looked like making a "gunner." I told him I would telephone to my brother-in-law when I got home, and if possible he would see her that afternoon. A few hours afterwards we motored out and bought the mare for £30, subject to my passing her sound next morning; the light was failing at the time. The following morning the mare was at my yard at the appointed hour, and I examined her carefully. Needless to say, I paid particular attention to her wind, but could notice nothing abnormal, except that after her gallop, which was a very severe one, she continued to breathe somewhat faster than usual for about an hour. To make sure that I was not being "had" I auscultated her lungs, coughed her, gave her hay and water, both of which she took, but still I could detect no unsoundness. I did not, however, examine her pupils.

My brother-in-law came out in the afternoon, and I told him that in my opinion she was sound. He had said to me the night before that she looked too good a mare for such a man to have. Having pulled her out again, and carefully looked over her, he told me that he believed she was "set." I stuck to my opinion, and said I had applied every test I knew, and could detect nothing wrong. Although he still "haed his doots" he took my advice, and paid for her. She was left with me for the night, and was to be sent on to Dublin next day. When I went out to her next morning she was the worst case of broken wind I have ever seen—her nostrils dilating and her sides going "bellows to mend." I forget exactly what my feelings were at the moment,

but I remember that my sorrow was lessened by the thought that my client was a relation.

Having communicated the sad news by telephone, my brother-in-law told me to do the best I could, and, if possible, to return the mare to the gipsy at a loss. I immediately advanced towards the moor, expecting to find that the enemy had broken up camp and retreated; but to my surprise I met him on the road driving in as gay as a lark. He was surprised to hear about the mare. Of course, he never doped her; he wouldn't know how; all she got that morning was a flour drink; she was always a good, sound mare. To make a long story short, he took her back and returned £20.

As regards the composition of the dope used for "setting pipers," I have heard, amongst other things, of doses of shot and fat. Hutyra and Marek say that temporary relief is often brought about by horse dealers by the internal administration of leaves, roots or seeds of plants containing atropine (*Atropa belladonna*, *Datura stramonium*, *Hyoscyamus niger*), and that experiments made in the Budapest clinic have shown that these plants do not merely reduce the frequency of respiration, but also abolish the double period and the forced character of the respirations, so that it may appear perfectly normal even in advanced cases. The effect is produced in fifteen minutes, and lasts a whole day.

It is only fair to mention that although my gipsy friend spoke with a cockney accent, I learned later that he answered to the distinctly Hibernian name of O'Gorman; so I don't know whether I have another grievance against the Saxon, or whether I was let down by one of my own.

#### RECTAL CONCRETIONS

Newly-born foals sometimes suffer from acute constipation due to the presence in the rectum of very hard, thick bars of dark-coloured meconium—mostly concentrated bile—which are actually too large to pass through the ring of the pelvis. By passing the finger into the rectum the end of the mass can be felt at the inlet of the pelvis. It can be pushed back, and when the foal forces, it returns to the same position; but it cannot come through.

In my experience repeated injections of warm soap solution and oil or the use of a spoon always fail to evacuate the bowel. I have found that by employing Hobday's bitch forceps, one of which is on the table, one can usually give relief in a very short time.

I first give a good injection of an emulsion of warm soap solution and oil, and finally one of oil alone. It will also help matters if, while the enemas are being given, the foal's hind feet are held in the air so as to raise the hind-quarters. This allows the oil to gravitate down the bowel and lubricate the contents. The closed forceps is then passed up the rectum till it meets the obstruction, when it is slowly opened as wide as possible and gently pushed forward till the handles touch the anus, and it is closed sufficiently to firmly grasp the mass. It is now slowly withdrawn, which sometimes requires some force, and the dung removed from the jaws. The process is repeated till the obstruction is completely removed, and another injection is generally followed by the passage of normal soft, yellow faeces.

What one naturally dreads is grasping the bowel between the jaws of the forceps and the obstruction, but, as well as I could judge, this has never happened; the shape of the forceps seems to prevent it.

Since adopting this treatment I have had eight of these cases, all of which recovered, and in which I consider the use of the forceps was the principal factor. If treated on any other lines I believe these foals would have succumbed, at least in my hands.

## UNDIAGNOSED : UNCERTIFIED.

Every veterinary surgeon, unless he wilfully blinds himself, sooner or later meets cases which he is unable to diagnose. Personally, I must confess that during the past sixteen years I have met many such. Of these the two which I am about to report are probably the most mysterious, and I am very anxious that members will give me their opinions, and possibly solve what I believe to be a very difficult problem. The account will, I fear, be a rather long one, as I wish to mention everything which can possibly assist in making a diagnosis, and there may, consequently, appear to be much unnecessary detail.

The time was the month of October, 1916. The subjects were "West Indian," a three year old thoroughbred bay gelding, and "Rodney Stone," a five year old thoroughbred chestnut gelding.

*History:* West Indian had been in training till the previous June, when he was noticed not to be well and was sent home for a rest. The weather being very warm, he was turned out to grass at night, and brought in during the day, when he received a feed of bruised oats and chopped hay.

Rodney Stone became his companion in August, and received the same treatment. They were the only two horses in the paddock, along with some cattle.

On October 21st both horses were brought in as usual at seven o'clock in the morning, each looking in perfect health. About eleven o'clock the stud groom heard West Indian "kicking up a shindy" in his box, and on opening the door found the colt stretched prostrate on his side, sweating all over and pawing occasionally. Thinking it was a case of colic, he administered a draught, and as there was no improvement after an hour he gave another. This not having the desired effect, he wired for me. I was away on another case at the time, but the message was sent on to me by telephone, and without returning home I went straight to the place.

I found the colt standing, looking very distressed, sweating profusely, and disinclined to move. All extremities were cold, the membranes injected, the artery corded, and the pulse barely perceptible. No peristaltic sounds could be heard at the flank; he was not blowing, but he sighed at each respiration, and pawed now and then. At times he threw himself down and lay prostrate for ten minutes or so, but he never rolled. The temperature was sub-normal, 98.3 degrees. He had passed dung normal in quantity and appearance, but had not staled from the time he came in. On examination per rectum, the bladder was found to be considerably distended, and as I had not a catheter with me I tried to empty it by pressure, but failed. Although extending my hand as far as possible into the abdominal cavity, I could not feel the pelvic flexure of the large bowel or any of the other intestines; it seemed as if they were drawn out of their usual positions. I expressed the opinion that it was probably a case of twist of the large intestine, and I considered it hopeless. However, I tried to administer a pint of linseed oil and two ounces of turpentine; but he resisted so much that we had to abandon the attempt. He got about half of the draught. I ordered him to be well sheeted and bandaged.

I went home for the catheter, etc. On my return, in about three hours' time, I found, to my surprise, that the pulse was much improved. Sweating had ceased, the bowels rumbling, and the temperature almost normal. I began to hope that my diagnosis and prognosis were wrong. The bladder was now enormously distended, and the passage of the catheter brought away a great quantity of urine, dark in colour, just like porter. I now believed I was dealing with an unusual case of acute azoturia. This was about the last thing I expected, as the usual history associated with this disease was altogether absent, and the life the colt had led seemed most unlikely to bring on such an attack.

As the patient was lying I administered a pint and a half of linseed oil and three ounces of turpentine, and gave a hypodermic injection of one grain of arecoline and half a grain of pilocarpine.

Strange to say, the latter had not the slightest effect, either as regards salivation or increased peristalsis. A week before I gave the same dose to a heavy draught horse suffering from stoppage, and he ran pints of saliva, and had three motions within one hour. The colt was also given an injection of several gallons of warm soap solution, and before leaving I ordered it to be repeated every two hours.

I again visited late that night, but the improvement was not maintained, and I gave no hope of recovery. On returning next morning I received the unpleasant news that one was gone and the other was now bad. This was Rodney Stone, West Indian's companion. He was found stretched in the paddock that morning, and affected in just the same way as his pal. He was brought in and was well clothed and bandaged. On examination I found the symptoms almost identical to those of the colt. The temperature was 98.4 degrees, and the passage of the catheter brought away porter-coloured urine, which left no doubt as to the nature of the two cases being similar. The pulse being too weak to administer arecoline or eserine, I gave a five-dram physic ball, and had rugs wrung out of hot water frequently laid across his loins. In view of the death of the colt, I said the betting was a hundred to one against him.

I then proceeded to make a *post-mortem* on West Indian, but beyond porter-like urine in the bladder, and a moist, tar-like appearance of the spleen on section, there was nothing abnormal, as far as I could see.

Rodney Stone's attack took a similar course to that of his companion, and he died early the following morning. The *post-mortem* was a repetition of the other, except that the spleen was normal.

The owner, who was in England, wired that every investigation should be made. My report on the two cases, and the viscera, including the stomachs and contents, were sent to the late Professor Mettam; but he considered it was a case for an analyst, and had them sent to Professor Ebrill, of the National University. Finally, Professor Ebrill reported that there was no evidence of malicious poisoning, and that in his opinion it was a case of either bacterial infection or fungus poisoning. Various extracts of the visceral contents were given to animals, but in no case could new information be obtained, though the animals were kept under close observation.

Subsequently, Professor Ebrill, in company with Mr. Doyle, Assistant Professor of Botany at the University, visited the stud farm, and inspected the paddock in which the two horses grazed. There was a portion of the paddock which was a recent addition, and the stud groom mentioned that this had been infested with fungus-growth, and even as late as their visit (which was in November) a few specimens were found by them.

These were analysed, but results were negative, and extracts of these given to animals produced no toxic symptoms, and in no case caused death. But in view of the fact that there was no chemical poisoning, and the symptoms corresponded closely to those of muscardial poisoning, they inclined to the latter view.

I may mention that the owner is an excellent employer, and very popular in the district. Probably there is no better managed stud farm in Ireland, and the stud groom is one of the best men of his class I have met.

In conclusion, I do not believe that horses fed on good grass, hay, and oats would eat mushrooms, poisonous or otherwise. Personally, I do not believe in the muscardial poisoning hypothesis, though I must confess I have no alternative theory to offer.

## SUBSCRIPTIONS TO R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following subscriptions for 1919 :—

	Mar. 11.
T. F. Arnold, Capt. R.A.V.C. (1918-19)	£2 2 0
J. W. Baxter, London, S.W.1	1 1 0
H. G. Bowes, Lt.-Col., RAVC.	1 1 0
A. Broad, London, W.	1 1 0
W. L. Cockburn, Liverpool	1 1 0
A. D. Lalor, Sleaford, Lincs.	1 1 0
W. E. Litt, Shrewsbury	1 1 0
R. Moore, Treorchy	1 1 0
Previously acknowledged	657 19 0
	£667 8 0

## FEES !

Sir,—With reference to the arrangements now being made to raise our fees, is it not all rather futile unless it is controlled by the National Society under the Council R.C.V.S. At present chaos exists—The Derbyshire Society enterprisingly draw up a minimum scale of fees; and subsequently the Royal Counties Society draw up another differing in various points, and also add 25% to these fees!

One finds that in a small radius V.S. are all charging differently—the one following the suggested scale unfortunately being exceptional, although it is obvious that lower fees are quite inadequate, if not unprofessional!

Until the question is taken up and controlled, I fail to see what can be done, as local authorities still continue to fix their own allowances, and if one protests—as I have done, against making important inspections and microscopic exams: and reports on contagious diseases for a fee of 5/-: it is in vain.

Personally, I fail to see why a complete fixed scale cannot be drawn up, as is done in the case of Solicitors, advertised in the Agricultural and other papers, and local authorities so notified, and except in exceptional circumstances, if these fees are not charged one should be liable to be reported to Council R.C.V.S. and dealt with accordingly.

Take the operation of castration; how can one possibly travel, say, five miles (often more) on two successive days, perform a responsible operation in the standing position for a fee of less than one guinea? Yet 10/6 is quite usually charged; and if one attempted to charge more than 15/- he would not be required very frequently, as Members are, I fear, not likely to charge more than 15/- at the most in the majority of districts!

Personally I am charging more than most of my neighbours, considerably; and yet I am somewhat under the Royal Counties scale in some cases: but I am quite prepared to risk losing clients rather than accept unremunerative and humiliating fees. In the case of local authorities one's hands are tied, as one cannot refuse an Inspectorship in one's own district.

I think Major Taylor got at the crux of the problem when he raised the point of the whole matter being controlled by the Council. I regret I cannot give my name, in case of being considered personal, but I am forced to mention facts actually existing. Before the war one could carry on, but in the present revolutionised times, with prices 50% to 100% raised, it is high time that the Profession as a whole moved, otherwise those holding out for fair and proper fees are in a somewhat unenviable position. It is also important for the future of the Profession—inability to give proper education to one's family will not help the already doubtful status held by the Veterinary Surgeon!—Yours etc.,

“WORRIED”

## QUACK MEDICINES AT SHOWS.

Sir,—Several questions occur to me on reading the report of that meeting at Derby in your current issue.

Did the meeting ever seriously consider the possibility that the Agricultural Societies, when forced to lose either the rents they receive from medicine vendors for their stall, or the no longer honorary services of veterinary surgeons, may decide to lose the latter? If they do so decide, what will the veterinary surgeons do then? Will they resign as they threaten, and risk permanent non-recognition at agricultural shows; or will they shift their ground, and practically own themselves to have been merely bluffing? And, whichever of these two courses they take, what will be the result for the profession? It seems to me that these Derbyshire practitioners are proposing a step, the consequences of which may be very different from those which they expect.—Yours truly,

“SCEPTIC”

## ARMY VETERINARY SERVICE

Mar. 8.

The Secretary of the War Office announces, by direction of the Secretary of State for War, that the Cavalry Regiments and Infantry Battalions comprised in the Army of the Rhine are as follows:—

\* \* \* \*

Mobile Vety. Sect., 13; Veterinary Hospitals, 3; R.A.V.C. Bact. Laboratory, 1; Vet. Evac. Station 5; Base Depôt of Vety. Stores.

Extracts from *London Gazette*,

WAR OFFICE, WHITEHALL, Mar. 5.

## REGULAR FORCES. ROYAL ARMY VETERINARY CORPS.

Temp. Capt. H. G. Bowes, F.R.C.V.S., relinquishes the actg. rank of Lt.-Col. (Feb. 8).

Capt. C. Drabble, (T.F.) relinquishes the actg. rank of Maj. on ceasing to comd. a Vety. Hosp. (Feb. 24).

Capt. and Bt. Maj. G. E. Tillyard to be actg. Maj. whilst comdg. a Vety. Hosp. (Feb. 24).

Temp. Capt. E. S. Dixon relinquishes his commn. on account of ill-health contracted on active service (March 6), and retains the rank of Capt.

Temp. Lt. to be temp. Capt.:—W. Walsh (Feb. 1); D. G. Wishart (Feb. 8); G. F. Banham (Feb. 10); W. L. Marshall (Feb. 18).

Mar. 6.

Temp. Capt. S. J. Motton, F.R.C.V.S., relinquishes his commn. on account of ill-health (March 7), and retains the rank of Capt.

Temp. Lt. W. W. Kerr to be temp. Capt. (Nov. 24, 1918).

Mar. 7.

Col. and Hon. Maj.-Gen. L. J. Blenkinsop, D.S.O., to be Maj.-Gen. (April 24, 1918), with seniority from Dec. 1, 1917 (substituted for notification in *Gazette* July 5, 1918).

Col. and Hon. Maj.-Gen. (temp. Brig.-Gen.) J. Moore, C.B., F.R.C.V.S., to be Maj.-Gen. (April 24, 1918), with seniority from Jan. 1, 1918.

Mar. 10.

Temp. Capt. T. H. Tranter relinquishes his commn. on account of ill-health (March 11), and retains the rank of Capt.

Temp. Lt. M. G. Connolly to be temp. Capt. (Feb. 19).

Mar. 8.

## OVERSEA FORCES.—CANADA.

No. 100823 Sgt. T. H. Hungerford to be temp. Capt. (Aug. 6, 1918) (substituted for *Gazette* notification Aug. 20, 1918, incorrectly specifying the promotion of this Officer as temp. Lt.)

## TERRITORIAL FORCE, ROYAL ARMY VETERINARY CORPS.

Mar. 5.

Capt. G. Dunlop-Martin relinquishes his commn. on acct. of ill-health contracted on active service (Mar. 6), and retains rank of Capt.

Mar. 11.

Capt. P. S. Thierry relinquishes his commn. on acct. of ill-health contracted on active service (March 12), and retains the rank of Capt.

## Personal.

FACER : HOLDING.—On the 22nd Feb. (by licence), at Christ Church, Luton, by Revd. W. Morgan, Capt. J. Facer, R.A.V.C., Luton, to Blanche (Peggie), daughter of Revd. W. Holding, formerly for many years Vicar of Moulton, Northants.

## OBITUARY.

ERNEST SEGER, M.R.C.V.S. Bolton, Lancs.

Graduated Edin: May, 1897.

KENNETH PHIN RANKIN, M.R.C.V.S., D.V.H., Board of Agriculture and Fisheries.

Graduated New Edin: May, 1904.

Mr. Rankin died at Plymouth on 7th March, from pneumonia. Aged 39.

GIRLING.—On the 1st March, at 48 Casualty Clearing Station, of broncho-pneumonia, after service throughout the war, Captain Theodore Augustus Girling, Canadian Army Veterinary Corps, of Saskatoon, sixth son of the late Revd. W. H. Girling and Mrs. Girling, of Lindley, Huddersfield, aged 42. Mentioned in dispatches.

FOREMAN.—On the 5th inst., Cecilia, wife of R. J. Foreman, M.R.C.V.S., High Cross, Tottenham.

## Another injustice to the Profession.

Description of the Crown Prince, taken from the new Almanach de Gotha (*Times*, March 12).

Prince William Victor August Ernest of Prussia, *ci-devant* Imperial Prince of the German Empire, Prince Royal of Prussia, Imperial Royal Highness, born at the Marble Palace, near Potsdam, on May 6th, 1882. Renounced his rights and succession to the Throne November 8th (December 1), 1918. Doctor in Law, University of Berlin; Doctor in Engineering, Polytechnic Schools, Berlin and Charlottenburg; Doctor in Veterinary Medicine, Higher Veterinary School, Berlin; formerly General of Infantry, etc.

## Louping Ill.

Several investigations have recently been carried out on this disease in sheep, but little progress. "In the last number of the *Journal of Comparative Pathology and Therapeutics* Sir Stewart Stockman, of the Board of Agriculture and Fisheries, discusses the rôle played by ticks in the production of louping ill. Particulars are given of 101 experiments conducted by the Board with a view of throwing light upon the cause, nature, and course of the disease. Sir S. Stockman is not inclined to think that the complaint in sheep has any close relationship to poliomyelitis in human beings. The disease is definitely tick-borne, and the infecting agent is not a toxin. It is transmitted by larval ticks (*Ixodius ricinus*) from females which have been feeding on the blood of infected sheep. It was also produced by adult ticks which had been fed as nymphs on infected animals and by inoculation of gland juice and blood from such animals. Arrangements are being made to test the practical value of protective inoculation in the case of adult sheep brought on to farms for the purpose of restocking, as well as in lambs born on the farms. The eradication of the tick suggests itself as one way of preventing the disease, and an intensive study of the life-history of the parasite is obviously a preliminary to the framing of an appropriate campaign."—*The Lancet*

No. 1602.

MARCH 22, 1919.

VOL. XXXI.

## VETERINARY EMPLOYMENT.

As the situation becomes clearer, we are beginning to be able to form some forecast of the developments of the near future. We can now see enough of some coming changes to consider their probable effect upon the profession.

The military proposals render it certain that our army will remain much larger than it was a few years back. This will have two effects upon us. More veterinary surgeons will be required for the army than in the old times; thus a field of veterinary work which for many years has been one of the most attractive to our young graduates, will be permanently expanded; and its conditions are more likely to improve than to deteriorate in the near future. This will mean a consequent reduction in the number of veterinary surgeons immediately available for civil life, with less danger of unemployment in that sphere.

The new responsibilities we are to undertake in non-European countries will operate in similar directions, though perhaps not to so great an extent. More veterinary surgeons will be wanted for overseas, with a corresponding decrease in the numbers left for home work.

In this country, two conflicting factors will be in action. Those branches of our work which arise from the luxuries of clients have been greatly diminished, and will not speedily regain their former importance. On the other hand, the economically important side of veterinary work will maintain the position into which it has now been brought, so far as private practice is concerned, while the veterinary public services will continue the steady progress they have made during the last generation. Again the reduced strength of the profession must be taken into account.

Broadly, there seems to be less danger of serious unemployment amongst us than in many other quarters. There must be some difficulties before the country settles down; but for the next few years it will probably be found that the supply of young graduates is falling below rather than exceeding the demand. This prospect was one of the reasons (and there were others) which justified the recent lenience of the Council with regard to some examination certificates. There is not likely to be any lack of veterinary work for a long time to come. There may be difficulty in obtaining an adequate reward for it; but so there is likely to be in most other fields of work.

## BACTERIAL INFECTION OF WOUNDS IN FRANCE.

In looking over a few old *Records* I have read with some interest two articles entitled "Bacterial infection of wounds in France." These articles are in the October and November issues and concern what is, in nearly all cases, a bite injury to commence with—practically every V. O. who has been in the army must be well acquainted with the condition.

I must say I was considerably surprised at the views expressed—my own, and the experience I have had of these lesions, being much at variance with what is described. A third contribution on the subject may therefore do no harm.

I have nothing to add as to origin. The frequency of these injuries here in France can only be attributed to the enforced idleness of animals standing on lines and unprotected from each other. Nearly all are caused by bites, and the location of the injury is almost always on the side of the neck in front of the shoulders.

As a result of this bite swelling develops. This swelling may be large or small, but usually it is full of fluid, fluctuating, and only skin deep. Sometimes there is considerable extravasation into the overlying skin, but commonly this is absent. More often than not there is no skin mark, or only some trifling abrasion, and incision in a fresh case (that is, of 24 hours or less) gives vent to a quantity of yellowish or reddish-yellow serous fluid containing deposited fibrinous matter. This, then, is the injury which constitutes the initial and starting point of the so-called "fibrous or bacterial" neck tumour.

Personally I have not witnessed the process of growth of one of these tumours, but have seen a fair number after they have been formed, and to my mind their growth can and should be avoided. In the first place, I have no hesitation in saying that primarily these "serous swellings" are not bacterial—and never should be, and that I cannot but regard the secondary unsightly fibroid callus as the result of either too timid treatment, or of treatment vastly over-zealous.

The tiny opening for syringing and drainage purposes which becomes choked and closed up between the times of dressing is about equal in its results to the curetting and packing method. Both effectually prevent adhesions and healing when the parts first vascularise or are about to do so, and both lead to an active and dense proliferation of the fascia lining the interior. With the best of intentions they effectively strangle Dame Nature in what I should term one of her best moods, and the

fibrous tumour with its unhealed centre is neither more nor less than a natural outcome of retardation of her healing effort.

I will give my reasons for so saying, and my theories, which are quite simple. To begin with, when a horse bites another one "on the side of the neck" he generally grabs and "hangs on"—you hear his teeth snap as the victim springs clear and frees the pinched-up skin—*skin only*, be it remembered—at this region. What has happened? Injury and tearing of the delicate areolar tissue connecting the skin to the flesh, bruising and sometimes laceration of minute blood vessels, especially veins. The lymphatics too should not be forgotten. Later there is natural inflammation of the injured part, natural effusion into the torn areolar spaces, and consequent separation of skin from the underlying muscle. The size of swelling will vary with the extent of the injury, the most important factors being, I think, the amount of torn or separated areolar space, and the bruising or thrombosing of return vessels. A subcutaneous fluid swelling is the result. This is of small size, usually disappears in a few days if left alone, but larger ones on the contrary tend to increase slowly but none the less surely, and may, as one of the writers observes, reach surprising proportions if not operated upon.

One has often asked oneself the question "Why does this fluid not absorb?" I am inclined to think that damaged venous or lymphatic return vessels offer the chief explanation of the phenomenon, in addition, the skin attachment of the area here involved is loose in character, and separation being once started further separation will proceed most readily. Movement is free and frequent, and some pumping action doubtless occurs, especially with the neck movements towards the uninjured side. No doubt, too, lymphic deposit on the inner surfaces of the cavity plays quite a part in hindering absorption and aiding the process of tumour enlargement. Be that as it may, what we get is a large and increasing swelling. Our aim and purpose is to get rid of this in the speediest possible way.

#### TREATMENT.

Perhaps I have theorised a little unnecessarily in the preceding paragraphs, but I thought it essential to the proper understanding of my ideas and the methods I have followed. We have a fluid subcutaneous swelling bounded on the one side by the firm musculature with its covering of fascia, on the other side by the inner skin surface, also smooth, dense, and clothed with fascia. The skin is intact, the contents aseptic.

If the swelling be small, leave it alone. As before said, it will absorb in a few days. But if it be of a larger size and not likely to disappear naturally within a reasonable time, open it. Nothing is to be gained—rather the reverse, by waiting for the swelling to become large, with further loss of valuable skin attachment. Swab the part with Iodine and make a free incision; as a general rule from the centre of the swelling to its lowest point. Now press the skin flat down and remove any extruding

fibrinous deposit, but on no account explore the wound in search for more. It is still aseptic; leave it so.

The animal should be placed by himself, or along with quiet neighbours, and twice daily the skin on each side of and above the wound is gently pressed flat down and the lips swabbed with Tr. Iodine—the first to ensure that no discharge or fluid is by chance being retained; the second to delay or hinder outside infection. Plugging, syringing, or bathing is strictly tabooed, the area being kept as nearly as may be immobile—that is—left alone. The only real essentials to success may be summarised now. They are:—

1. That the preliminary incision or incisions be so placed, and of such extent, that until the wound is dry and has ceased discharging, no fluid or discharge can at any time be retained.

2. That the interior of the wound be not disturbed.

Further than these, nothing really matters.

One must remember in dealing with these cases, that both sides of the wound cavity are, to commence with, smooth and coated with fascia; blood and capillary vessels are lacking, and, compared with the usual flesh wound, conditions for natural healing are in consequence not so satisfactory. This disadvantage, however, is only temporary, the surfaces rapidly vascularise, and, providing the little attachments present, or forming, are left intact (and a few most valuable strands of tissue are nearly always there to begin with—if not thoughtlessly removed or broken down) healing follows on normal lines. Also, in our favour in dealing with these subcutaneous wounds, as compared with wounds generally, the wound cavity is, until we incise it, aseptic and the incision made is exactly where, and of the extent, we would have it. Drainage therefore is perfect and constant, and with perfect drainage how many wounds ever cause trouble? Practically none.

For the first two or three days discharge is fairly profuse, then it rapidly diminishes, and ceases in from about a week to a fortnight, depending on the size of the cavity. In its place is left a flat slightly raised swelling, showing the yet unhealed cut in its lower half. This swelling also in its turn soon disappears.

Outside germ contamination may or may not occur, but when it does happen it is usually not until 2 or 3 days after opening up, and is invariably mild and confined to the lower parts of the wound. Indeed a little pus infection at this period does not appear to materially alter the progress or result.

Following the above method I have had no trouble with these cases, and recovery has been invariably satisfactory. No blemish or thickening remains. In a few, crinkling of the skin persisted for 3 or 4 weeks, but this happened only in those where the undermining had been very extensive. Provided that harness does not interfere with the affected part, the animal may be used, if wanted, as soon as all discharge has ceased, but care should be taken not to return him too early to the lines—alongside the very horse, perhaps, that bit him in

the first instance. For a little while, the injured part would readily yield to a second bite.

In conclusion, I may say I have advocated this treatment to several V. O. I have met here in France; and to those who have not tried it, or who have trouble with these cases, I can only say that if they adopt this treatment they will have no after regrets. Indeed, I feel sure they will soon come to regard this injury, as I do, as one of only minor importance.

JOHN ROBSON, M.R.C.V.S. Capt. A. A. V.C.  
27th Feb. 1919.

#### ABSTRACTS FROM FOREIGN JOURNALS.

##### SUDDEN DEATH IN THORACIC EFFUSIONS.

Sudden deaths in the course of thoracic effusions, which are sometimes reported in man, may also be seen in the domestic animals. Ducasse reported a case in a horse in 1908, and Petit two cases in dogs in 1913. Lasserre and Lesbouyries, in *Revue Vétérinaire* for 1914, reported the two following cases in cats, which occurred within five months.

The first animal, which presented clinical symptoms of pleurisy with effusion, died at the moment when the rectal temperature was being taken with a view to the tuberculin test. The animal, after struggling violently, died suddenly. Post mortem examination confirmed the diagnosis, revealing tuberculous pleurisy with pulmonary caverns.

The second cat showed a bilateral dulness of the chest to percussion. While auscultation was being carried out, the animal suddenly fell into syncope and died. This cat was affected with pyo-pneumothorax of non-tuberculous nature; microscopic tests and the inoculation of the guinea-pig both gave negative results.

In these two cases it seems that the syncope, which was facilitated by the abundance of the pleural effusion, had its origin in the very acute agitation of the first subject at the moment when the temperature was taken; and in the manipulations of auscultation and percussion in the second subject.

The practical conclusion to be drawn is that, in the case of any animal suspected of being affected with a pleural effusion (and the respiratory discordance should awaken the suspicion) the veterinarian should exercise extreme care in auscultating and percussing, and avoid either agitation of the animal, excessive pressure, or sudden changes in the different attitudes necessary for the examination.

A Belgian commentator adds the three following cases from his own recent experience. The first was a dog affected with purulent pleurisy following upon distemper. One day this animal was placed upon his back, and was then attacked by a fatal syncope. The other two cases were in cats showing symptoms of pleurisy. Both died in the course of manipulations necessary for the examination of the chest; and both were found post mortem to be affected with tuberculosis.—(*Annales de Médecine Vétérinaire*).

#### VETERINARY MEDICAL ASSOCIATION OF IRELAND.

[NATIONAL V.M.A.—IRISH BRANCH.]

(Concluded from p. 322.)

##### SPECIMENS.

The CHAIRMAN: Before you discuss Mr. Magee's paper I wish to put a few specimens on the table. Unfortunately there are very few of these brought forward at our meetings.

##### *Natural repair of Fractured Femur.*

The first is the femur of a collie dog. Some years ago the dog was sent to me suffering from a fracture of the femur. Being of the opinion that there was very little chance of setting it properly in the ordinary way, I suggested to the owner to let me put the dog under chloroform, cut down on the fracture and wire the broken ends together. He didn't like the idea and decided to let the patient take his chance.

I was informed that a couple of years previously the animal had broken the same bone, and that it had united by itself.

The owner, adopting the same treatment again, let the dog "have his fling" and, strange to say, union again took place spontaneously. I have seen the dog many times chasing up and down the village, and the only sign of his having had a fracture was a pronounced lameness. Last week he bit a child, and his master sent him to me to be destroyed, which I did with chloroform. By examining the bone you can see that the unions after the fractures were bad, with the result that the bone seems to be twice as thick as its fellow of the other leg, and nearly an inch shorter.

##### *Urinary Calculus in a Bull.*

The next is portion of the penis of a bullock, showing a very good specimen of a calculus *in situ*. I asked the owner to let me operate, but as the animal was fairly fat he preferred to send him to the butcher. The usual symptoms of urethral calculus are loss of appetite, wasting, frequent urination—every half hour or so, kicking at the belly and switching the tail. There was, however, one symptom in connection with this case which I have never observed before, nor have I seen it mentioned in any text book. The bullock with his fore feet would sometimes scrape away the grass for about three or four feet and having made a shallow hole in the clay would lie down with his belly in the hole.

Mr. HEALY: He improvised a catheter.

Mr. MAGEE: I think his idea was to try and cool the abdomen.

##### *Impaction in a Dog.*

The third specimen is one which I found in the intestine of a terrier that died from stoppage. When brought to me the dog was *in extremis*, and I told the owner that I could not really say what was wrong with him, but that there was no hope for him. He died a few hours later. I found a couple of feet of the small bowel packed with what at first seemed to be some new form of tape worm. It completely puzzled me. On examining it closely I found it consisted of numerous thin, tape-like strips of rubber. A young lad who was helping me said that it was the inside of a golf ball. The owner afterwards told me that the terrier was very fond of taking up golf balls in his mouth and playing with them.

##### *A useful Instrument.*

This is an instrument called Malloch's Dent wedge, which possibly some of the members may not have seen. I think it is one of the best, and cheapest mouth gags on the market. It is simple, and cannot go out of order. It takes up very little room, and is equally serviceable for horses and cattle. Yesterday I used it in a bad case

of choking in a cow. The obstruction was a large raw potato which was firmly wedged in the commencement of the gullet. It was too large to push down with the probang, and I found it impossible to get a proper grip of it with my fingers to pull it back. Having tried various dodges for more than half an hour and failed, I finally succeeded by getting an assistant to press hard with his two closed fists on either side of the gullet beneath the obstruction and thus to gradually force it up a little. This enabled me to get my fingers around the potato and to pull it out, to the great delight of the poor woman who owned the cow.

I have found this gag extremely useful on many occasions, and I think it is well worth bringing under the notice of the members.

Mr. HEALY: I have been using it for some time, and it is of great advantage in rasping horses' teeth. If you put it in on the near side while working on the off side you won't have half the trouble. I got a tooth rasp made by Sharp and Smith of Chicago. They have two kinds—one that rotates and a flat one. Often if you use the usual gag the horse will get cross.

Mr. MAGEE: A young horse objects less to it than any other gag.

Mr. HEALY: It is also very useful if you get a snoring case.

#### *Blue Urine.*

Mr. MAGEE: The next specimen is, in my experience unique. It is blue coloured hair, which I have taken from the prepuce of a bullock. Standing a short distance from the beast and looking beneath, one got the impression that there was a blue, jelly-like substance hanging from the prepuce. The hairs, as you see, appear to be covered with a thin coating of lime salts, blue in colour. A short history of the case may be interesting.

He was a two-year-old bullock. A short time after he was skulled he commenced to do badly. He kept away from his companions, and sometimes walked around in large circles. The owner said there was also a slight discharge from the butt of the right horn core. When I saw him the discharge had stopped, but the other symptoms could be observed. Suspecting sinus trouble I tested by tapping, but there was no difference in the sounds, and no signs of bulging or pain on pressure. Thinking that possibly there still might be trouble in the sinus, I decided to make, a few days later, an exploratory opening through the horn core and to pass down a long probe into the sinus. However, before I could do this I got an attack of the "flu" and was laid up for a month. It was during this time that the herd, a most trustworthy man, observed the bullock passing blue water. He said it was just the same as when his wife mixed Reckitt's blue with water for washing. The beast passed the blue water for about a week; it then became normal in colour again.

We already have red water and black water, but we must now add blue water to the list. Although I did not actually see the beast passing the blue water, I do not doubt the herd's word for a moment—he could have no object in concocting such a story—and the blue colouration on the hairs of the prepuce are, I consider, a convincing proof of the truth of his statement. When I saw the bullock again he seemed to be picking up and showed no signs of head trouble, and although still poor in condition I advised the owner to "let well enough alone".

Mr. HEALY: If you can have blue milk you can have blue urine. I have seen blue milk from cows.

#### *Intussusception.*
